

--- title: "PgBouncer" draft: false ---

# pgBouncer - A Lightweight Connection Pooler for PostgreSQL

## PgBouncer

Lightweight connection pooler for PostgreSQL.

Homepage

<https://pgbouncer.github.io>

Sources, bugtracking

<https://github.com/pgbouncer/pgbouncer>

## Building

PgBouncer depends on few things to get compiled:

- [GNU Make](#) 3.81+
- [libevent](#) 2.0
- (optional) [OpenSSL](#) 1.0.1 for TLS support.
- (optional) [c-ares](#) as alternative to libevent's evdns.

When dependencies are installed just run:

```
$ ./configure --prefix=/usr/local --with-libevent=libevent-prefix
$ make
$ make install
```

If you are building from git, or are building for Windows, please see separate build instructions below.

## DNS lookup support

Starting from PgBouncer 1.4, it does hostname lookups at connect time instead just once at config load time. This requires proper async DNS implementation. Following list shows supported backends and their probing order:

backend	parallel	EDNS0 (1)	/etc/hosts	SOA lookup (2)	note
c-ares	yes	yes	yes	yes	ipv6+CNAME buggy in <=1.10
udns	yes	yes	no	yes	ipv4-only
evdns, libevent 2.x	yes	no	yes	no	does not check /etc/hosts updates
getaddrinfo_a, glibc 2.9+	yes	yes (3)	yes	no	N/A on non-linux
getaddrinfo, libc	no	yes (3)	yes	no	N/A on win32, requires pthreads
evdns, libevent 1.x	yes	no	no	no	buggy

1. EDNS0 is required to have more than 8 addresses behind one hostname.
2. SOA lookup is needed to re-check hostnames on zone serial change
3. To enable EDNS0, add *options edns0* to */etc/resolv.conf*

*./configure* also has flags *--enable-evdns* and *--disable-evdns* which turn off automatic probing and force use of either *evdns* or *getaddrinfo\_a()* .

## Building from GIT

Building PgBouncer from GIT requires that you fetch libusual submodule and generate the header and config files before you can run configure:

```
$ git clone https://github.com/pgbouncer/pgbouncer.git
$ cd pgbouncer
$ git submodule init
$ git submodule update
$ ./autogen.sh
```

```
$ ./configure ...  
$ make  
$ make install
```

Additional packages required: autoconf, automake, libtool, autoconf-archive, python-docutils, and pkg-config.

## Building for WIN32

At the moment only build env tested is MINGW32 / MSYS. Cygwin and Visual \$ANYTHING are untested. Libevent 2.x is required for DNS hostname lookup.

Then do the usual:

```
$ ./configure ...  
$ make
```

If cross-compiling from Unix:

```
$ ./configure --host=i586-mingw32msvc ...
```

## Running on WIN32

Running from command-line goes as usual, except -d (daemonize), -R (reboot) and -u (switch user) switches will not work.

To run pgbouncer as a Windows service, you need to configure *service\_name* parameter to set name for service. Then:

```
$ pgbouncer -regservice config.ini
```

To uninstall service:

```
$ pgbouncer -unregservice config.ini
```

To use Windows Event Log, set "syslog = 1" in config file. But before you need to register pgbevent.dll:

```
$ regsvr32 pgbevent.dll
```

To unregister it, do:

```
$ regsvr32 /u pgbevent.dll
```

--- title: "Usage" draft: false ---

## Synopsis

```
pgbouncer [-d][-R][-v][-u user]
pgbouncer -V|-h
```

On Windows computers, the options are:

```
pgbouncer.exe [-v][-u user]
pgbouncer.exe -V|-h
```

Additional options for setting up a Windows service:

```
pgbouncer.exe --regservice
pgbouncer.exe --unregservice
```

## DESCRIPTION

**pgbouncer** is a PostgreSQL connection pooler. Any target application can be connected to **pgbouncer** as if it were a PostgreSQL server, and **pgbouncer** will create a connection to the actual server, or it will reuse one of its existing connections.

The aim of **pgbouncer** is to lower the performance impact of opening new connections to PostgreSQL.

In order not to compromise transaction semantics for connection pooling, **pgbouncer** supports several types of pooling when rotating connections:

### Session pooling

Most polite method. When client connects, a server connection will be assigned to it for the whole duration the client stays connected. When the client disconnects, the server connection will be put back into the pool. This is the default method.

### Transaction pooling

A server connection is assigned to client only during a transaction. When PgBouncer notices that transaction is over, the server connection will be put back into the pool.

### Statement pooling

Most aggressive method. The server connection will be put back into pool immediately after a query completes. Multi-statement transactions are disallowed in this mode as they would break.

The administration interface of **pgbouncer** consists of some new SHOW commands available when connected to a special 'virtual' database **pgbouncer**.

## Quick-start

Basic setup and usage as following.

1. Create a pgbouncer.ini file. Details in **pgbouncer(5)**. Simple example:

```
[databases]
template1 = host=127.0.0.1 port=5432 dbname=template1

[pgbouncer]
listen_port = 6543
listen_addr = 127.0.0.1
auth_type = md5
auth_file = users.txt
logfile = pgbouncer.log
pidfile = pgbouncer.pid
admin_users = someuser
```

2. Create users.txt file that contains users allowed in:

```
"someuser" "same_password_as_in_server"
```

3. Launch **pgbouncer** :

```
$ pgbouncer -d pgbouncer.ini
```

4. Have your application (or the **psql** client) connect to **pgbouncer** instead of directly to PostgreSQL server:

```
$ psql -p 6543 -U someuser template1
```

5. Manage **pgbouncer** by connecting to the special administration database **pgbouncer** and issuing `show help`; to begin:

```
$ psql -p 6543 -U someuser pgbouncer
pgbouncer=# show help;
NOTICE: Console usage
DETAIL:
SHOW [HELP|CONFIG|DATABASES|FDS|POOLS|CLIENTS|SERVERS|SOCKETS|LISTS|VERSION]
SET key = arg
RELOAD
PAUSE
SUSPEND
RESUME
SHUTDOWN
```

6. If you made changes to the `pgbouncer.ini` file, you can reload it with:

```
pgbouncer=# RELOAD;
```

## Command line switches

- d Run in background. Without it the process will run in foreground. Note: Does not work on Windows, **pgbouncer** need to run as service there.
- R Do an online restart. That means connecting to the running process, loading the open sockets from it, and then using them. If there is no active process, boot normally. Note: Works only if OS supports Unix sockets and the `unix_socket_dir` is not disabled in config. Does not work on Windows machines. Does not work with TLS connections, they are dropped.
- u *user* Switch to the given user on startup.
- v Increase verbosity. Can be used multiple times.
- q Be quiet - do not log to stdout. Note this does not affect logging verbosity, only that stdout is not to be used. For use in `init.d` scripts.
- V Show version.
- h Show short help.
- regservice Win32: Register pgbouncer to run as Windows service. The **service\_name** config parameter value is used as name to register under.
- unregservice Win32: Unregister Windows service.

## Admin console

The console is available by connecting as normal to the database **pgbouncer** :

```
$ psql -p 6543 pgbouncer
```

Only users listed in configuration parameters **admin\_users** or **stats\_users** are allowed to login to the console. (Except when `auth_mode=any` , then any user is allowed in as a `stats_user`.)

Additionally, the username **pgbouncer** is allowed to log in without password, if the login comes via Unix socket and the client has same Unix user uid as the running process.

## Show commands

The **SHOW** commands output information. Each command is described below.

### SHOW STATS;

Shows statistics.

database

Statistics are presented per database.

total\_requests

Total number of SQL requests pooled by **pgbouncer** .

total\_received

Total volume in bytes of network traffic received by **pgbouncer** .

total\_sent

Total volume in bytes of network traffic sent by **pgbouncer** .

total\_query\_time

Total number of microseconds spent by **pgbouncer** when actively connected to PostgreSQL.

avg\_req

Average requests per second in last stat period.

avg\_recv

Average received (from clients) bytes per second.

avg\_sent

Average sent (to clients) bytes per second.

avg\_query

Average query duration in microseconds.

## SHOW SERVERS;

type

S, for server.

user

Username **pgbouncer** uses to connect to server.

database

Database name.

state

State of the pgbouncer server connection, one of **active** , **used** or **idle** .

addr

IP address of PostgreSQL server.

port

Port of PostgreSQL server.

local\_addr

Connection start address on local machine.

local\_port

Connection start port on local machine.

connect\_time

When the connection was made.

request\_time

When last request was issued.

ptr

Address of internal object for this connection. Used as unique ID.

link

Address of client connection the server is paired with.

remote\_pid

Pid of backend server process. In case connection is made over unix socket and OS supports getting process ID info, it's OS pid. Otherwise it's extracted from cancel packet server sent, which should be PID in case server is Postgres, but it's a random number in case server is another PgBouncer.

## SHOW CLIENTS;

type

C, for client.

user

Client connected user.

database

Database name.

state

State of the client connection, one of **active** , **used** , **waiting** or **idle** .

addr

IP address of client.

port

Port client is connected to.

local\_addr

Connection end address on local machine.

local\_port

Connection end port on local machine.

connect\_time

Timestamp of connect time.

request\_time

Timestamp of latest client request.

ptr

Address of internal object for this connection. Used as unique ID.

link

Address of server connection the client is paired with.

remote\_pid

Process ID, in case client connects over UNIX socket and OS supports getting it.

## SHOW POOLS;

A new pool entry is made for each couple of (database, user).

database

Database name.

user

User name.

cl\_active

Client connections that are linked to server connection and can process queries.

cl\_waiting

Client connections have sent queries but have not yet got a server connection.

sv\_active

Server connections that linked to client.

sv\_idle

Server connections that unused and immediately usable for client queries.

sv\_used

Server connections that have been idle more than *server\_check\_delay* , so they needs *server\_check\_query* to run on it before it can be used.

sv\_tested

Server connections that are currently running either *server\_reset\_query* or *server\_check\_query* .

sv\_login

Server connections currently in logging in process.

maxwait

How long the first (oldest) client in queue has waited, in seconds. If this starts increasing, then the current pool of servers does not handle requests quick enough. Reason may be either overloaded server or just too small of a **pool\_size** setting.

pool\_mode

The pooling mode in use.

## SHOW LISTS;

Show following internal information, in columns (not rows):

databases

Count of databases.

users

Count of users.

pools

Count of pools.

free\_clients

Count of free clients.

used\_clients

Count of used clients.

login\_clients

Count of clients in **login** state.

free\_servers

Count of free servers.

used\_servers

Count of used servers.

## SHOW USERS;

name

The user name

pool\_mode

The user's override pool\_mode, or NULL if the default will be used instead.

## SHOW DATABASES;

name

Name of configured database entry.

host

Host pgbouncer connects to.

port

Port pgbouncer connects to.  
database

Actual database name pgbouncer connects to.  
force\_user

When user is part of the connection string, the connection between pgbouncer and PostgreSQL is forced to the given user, whatever the client user.

pool\_size

Maximum number of server connections.

pool\_mode

The database's override pool\_mode, or NULL if the default will be used instead.

## SHOW FDS;

Internal command - shows list of fds in use with internal state attached to them.

When the connected user has username "pgbouncer", connects through Unix socket and has same UID as running process, the actual fds are passed over the connection. This mechanism is used to do an online restart. Note: This does not work on Windows machines.

This command also blocks internal event loop, so it should not be used while PgBouncer is in use.

fd

File descriptor numeric value.

task

One of **pooler** , **client** or **server** .

user

User of the connection using the FD.

database

Database of the connection using the FD.

addr

IP address of the connection using the FD, **unix** if a unix socket is used.

port

Port used by the connection using the FD.

cancel

Cancel key for this connection.

link

fd for corresponding server/client. NULL if idle.

## SHOW CONFIG;

Show the current configuration settings, one per row, with following columns:

key

Configuration variable name

value

Configuration value

changeable

Either **yes** or **no** , shows if the variable can be changed while running. If **no** , the variable can be changed only boot-time.

## SHOW DNS\_HOSTS;

Show hostnames in DNS cache.

hostname

Host name.

ttd

How many seconds until next lookup.

addrs

Comma separated list of addresses.

## SHOW DNS\_ZONES

Show DNS zones in cache.

zonename

Zone name.

serial

Current serial.

count

Hostnames belonging to this zone.

## Process controlling commands

### **PAUSE [db];**

PgBouncer tries to disconnect from all servers, first waiting for all queries to complete. The command will not return before all queries are finished. To be used at the time of database restart.

If database name is given, only that database will be paused.

### **DISABLE db;**

Reject all new client connections on the given database.

### **ENABLE db;**

Allow new client connections after a previous **DISABLE** command.

### **KILL db;**

Immediately drop all client and server connections on given database.

### **SUSPEND;**

All socket buffers are flushed and PgBouncer stops listening for data on them. The command will not return before all buffers are empty. To be used at the time of PgBouncer online reboot.

### **RESUME [db];**

Resume work from previous **PAUSE** or **SUSPEND** command.

### **SHUTDOWN;**

The PgBouncer process will exit.

### **RELOAD;**

The PgBouncer process will reload its configuration file and update changeable settings.

## Signals

SIGHUP

Reload config. Same as issuing command **RELOAD;** on console.

SIGINT

Safe shutdown. Same as issuing **PAUSE;** and **SHUTDOWN;** on console.

SIGTERM

Immediate shutdown. Same as issuing **SHUTDOWN;** on console.

## Libevent settings

From libevent docs:

It is possible to disable support for epoll, kqueue, devpoll, poll or select by setting the environment variable `EVENT_NOEPOLL`, `EVENT_NOKQUEUE`, `EVENT_NODEVPOLL`, `EVENT_NOPOLL` or `EVENT_NOSELECT`, respectively.

By setting the environment variable `EVENT_SHOW_METHOD`, libevent displays the kernel notification method that it uses.

## See also

pgbouncer(5) - manpage of configuration settings descriptions.

<https://pgbouncer.github.io/>

<https://wiki.postgresql.org/wiki/PgBouncer>

--- title: "Configuration" draft: false ---

## Description

Config file is in "ini" format. Section names are between "[" and "]". Lines starting with ";" or "#" are taken as comments and ignored. The characters ";" and "#" are not recognized when they appear later in the line.

## Generic settings

### logfile

Specifies log file. Log file is kept open so after rotation kill -HUP or on console RELOAD; should be done. Note: On Windows machines, the service must be stopped and started.

Default: not set.

### pidfile

Specifies the pid file. Without a pidfile, daemonization is not allowed.

Default: not set.

### listen\_addr

Specifies list of addresses, where to listen for TCP connections. You may also use \* meaning "listen on all addresses". When not set, only Unix socket connections are allowed.

Addresses can be specified numerically (IPv4/IPv6) or by name.

Default: not set

### listen\_port

Which port to listen on. Applies to both TCP and Unix sockets.

Default: 6432

### unix\_socket\_dir

Specifies location for Unix sockets. Applies to both listening socket and server connections. If set to an empty string, Unix sockets are disabled. Required for online reboot (-R) to work. Note: Not supported on Windows machines.

Default: /tmp

### unix\_socket\_mode

Filesystem mode for unix socket.

Default: 0777

### unix\_socket\_group

Group name to use for unix socket.

Default: not set

### user

If set, specifies the Unix user to change to after startup. Works only if PgBouncer is started as root or if it's already running as given user.

Note: Not supported on Windows machines.

Default: not set

### auth\_file

The name of the file to load user names and passwords from. The file format is the same as the PostgreSQL 8.x pg\_auth/pg\_pwd file, so this setting can be pointed directly to one of those backend files. Since version 9.0, PostgreSQL does not use such text file, so it must be generated manually. See section [Authentication file format](#) below about details.

Default: not set.

## **auth\_hba\_file**

HBA configuration file to use when [auth\\_type](#) is hba . Supported from version 1.7 onwards.

Default: not set

## **auth\_type**

How to authenticate users.

hba

Actual auth type is loaded from [auth\\_hba\\_file](#) . This allows different authentication methods different access paths. Example: connection over unix socket use peer auth method, connection over TCP must use TLS. Supported from version 1.7 onwards.

cert

Client must connect over TLS connection with valid client cert. Username is then taken from CommonName field from certificate.

md5

Use MD5-based password check. [auth\\_file](#) may contain both MD5-encrypted or plain-text passwords. This is the default authentication method.

plain

Clear-text password is sent over wire. Deprecated.

trust

No authentication is done. Username must still exist in [auth\\_file](#) .

any

Like the trust method, but the username given is ignored. Requires that all databases are configured to log in as specific user. Additionally, the console database allows any user to log in as admin.

## **auth\_query**

Query to load user's password from database.

Direct access to pg\_shadow requires admin rights. It's preferable to use non-admin user that calls SECURITY DEFINER function instead.

Default: SELECT username, passwd FROM pg\_shadow WHERE username=\$1

## **pool\_mode**

Specifies when a server connection can be reused by other clients.

session

Server is released back to pool after client disconnects. Default.

transaction

Server is released back to pool after transaction finishes.

statement

Server is released back to pool after query finishes. Long transactions spanning multiple statements are disallowed in this mode.

## **max\_client\_conn**

Maximum number of client connections allowed. When increased then the file descriptor limits should also be increased. Note that actual number of file descriptors used is more than max\_client\_conn. Theoretical maximum used is:

$\text{max\_client\_conn} + (\text{max\_pool\_size} * \text{total\_databases} * \text{total\_users})$

if each user connects under its own username to server. If a database user is specified in connect string (all users connect under same username), the theoretical maximum is:

$\text{max\_client\_conn} + (\text{max\_pool\_size} * \text{total\_databases})$

The theoretical maximum should be never reached, unless somebody deliberately crafts special load for it.

Still, it means you should set the number of file descriptors to a safely high number.

Search for ulimit in your favourite shell man page. Note: ulimit does not apply in a Windows environment.

Default: 100

### **default\_pool\_size**

How many server connections to allow per user/database pair. Can be overridden in the per-database configuration.

Default: 20

### **min\_pool\_size**

Add more server connections to pool if below this number. Improves behaviour when usual load comes suddenly back after period of total inactivity.

Default: 0 (disabled)

### **reserve\_pool\_size**

How many additional connections to allow to a pool. 0 disables.

Default: 0 (disabled)

### **reserve\_pool\_timeout**

If a client has not been serviced in this many seconds, pgbouncer enables use of additional connections from reserve pool. 0 disables.

Default: 5.0

### **max\_db\_connections**

Do not allow more than this many connections per-database (regardless of pool - i.e. user). It should be noted that when you hit the limit, closing a client connection to one pool will not immediately allow a server connection to be established for another pool, because the server connection for the first pool is still open. Once the server connection closes (due to idle timeout), a new server connection will immediately be opened for the waiting pool.

Default: unlimited

### **max\_user\_connections**

Do not allow more than this many connections per-user (regardless of pool - i.e. user). It should be noted that when you hit the limit, closing a client connection to one pool will not immediately allow a server connection to be established for another pool, because the server connection for the first pool is still open. Once the server connection closes (due to idle timeout), a new server connection will immediately be opened for the waiting pool.

### **server\_round\_robin**

By default, pgbouncer reuses server connections in LIFO (last-in, first-out) manner, so that few connections get the most load. This gives best performance if you have a single server serving a database. But if there is TCP round-robin behind a database IP, then it is better if pgbouncer also uses connections in that manner, thus achieving uniform load.

Default: 0

### **ignore\_startup\_parameters**

By default, PgBouncer allows only parameters it can keep track of in startup packets - client\_encoding , datestyle , timezone and standard\_conforming\_strings .

All others parameters will raise an error. To allow others parameters, they can be specified here, so that pgbouncer knows that they are handled by admin and it can ignore them.

Default: empty

## **disable\_pgexec**

Disable Simple Query protocol (PQexec). Unlike Extended Query protocol, Simple Query allows multiple queries in one packet, which allows some classes of SQL-injection attacks. Disabling it can improve security. Obviously this means only clients that exclusively use Extended Query protocol will stay working.

Default: 0

## **application\_name\_add\_host**

Add the client host address and port to the application name setting set on connection start. This helps in identifying the source of bad queries etc. This logic applies only on start of connection, if application\_name is later changed with SET, pgbouncer does not change it again.

Default: 0

## **conffile**

Show location of current config file. Changing it will make PgBouncer use another config file for next RELOAD / SIGHUP .

Default: file from command line.

## **service\_name**

Used on win32 service registration.

Default: pgbouncer

## **job\_name**

Alias for [service\\_name](#) .

# **Log settings**

## **syslog**

Toggles syslog on/off As for windows environment, eventlog is used instead.

Default: 0

## **syslog\_ident**

Under what name to send logs to syslog.

Default: pgbouncer (program name)

## **syslog\_facility**

Under what facility to send logs to syslog. Possibilities: auth , authpriv , daemon , user , local0-7 .

Default: daemon

## **log\_connections**

Log successful logins.

Default: 1

## **log\_disconnections**

Log disconnections with reasons.

Default: 1

## **log\_pooler\_errors**

Log error messages pooler sends to clients.

Default: 1

## **stats\_period**

Period for writing aggregated stats into log.

Default: 60

## **verbose**

Increase verbosity. Mirrors "-v" switch on command line. Using "-v -v" on command line is same as *verbose=2* in config.

Default: 0

# **Console access control**

## **admin\_users**

Comma-separated list of database users that are allowed to connect and run all commands on console. Ignored when [auth\\_type](#) is any , in which case any username is allowed in as admin.

Default: empty

## **stats\_users**

Comma-separated list of database users that are allowed to connect and run read-only queries on console. That means all SHOW commands except SHOW FDS.

Default: empty.

# **Connection sanity checks, timeouts**

## **server\_reset\_query**

Query sent to server on connection release, before making it available to other clients. At that moment no transaction is in progress so it should not include ABORT or ROLLBACK .

The query is supposed to clean any changes made to database session so that next client gets connection in well-defined state. Default is DISCARD ALL which cleans everything, but that leaves next client no pre-cached state. It can be made lighter, eg DEALLOCATE ALL to just drop prepared statements, if application does not break when some state is kept around.

When transaction pooling is used, the [server\\_reset\\_query](#) is not used, as clients must not use any session-based features as each transaction ends up in different connection and thus gets different session state.

Default: DISCARD ALL

## **server\_reset\_query\_always**

Whether [server\\_reset\\_query](#) should be run in all pooling modes. When this setting is off (default), the [server\\_reset\\_query](#) will be run only in pools that are in sessions-pooling mode. Connections in transaction-pooling mode should not have any need for reset query.

It is workaround for broken setups that run apps that use session features over transaction-pooled pgbouncer. It changes non-deterministic breakage to deterministic breakage - client always lose their state after each transaction.

Default: 0

## **server\_check\_delay**

How long to keep released connections available for immediate re-use, without running sanity-check queries on it. If 0 then the query is ran always.

Default: 30.0

## **server\_check\_query**

Simple do-nothing query to check if the server connection is alive.

If an empty string, then sanity checking is disabled.

Default: SELECT 1;

## **server\_lifetime**

The pooler will try to close server connections that have been connected longer than this. Setting it to 0 means the connection is to be used only once, then closed. [seconds]

Default: 3600.0

## **server\_idle\_timeout**

If a server connection has been idle more than this many seconds it will be dropped. If 0 then timeout is disabled. [seconds]

Default: 600.0

## **server\_connect\_timeout**

If connection and login won't finish in this amount of time, the connection will be closed. [seconds]

Default: 15.0

## **server\_login\_retry**

If login failed, because of failure from connect() or authentication that pooler waits this much before retrying to connect. [seconds]

Default: 15.0

## **client\_login\_timeout**

If a client connects but does not manage to login in this amount of time, it will be disconnected. Mainly needed to avoid dead connections stalling SUSPEND and thus online restart. [seconds]

Default: 60.0

## **autodb\_idle\_timeout**

If the automatically created (via "\*) database pools have been unused this many seconds, they are freed. The negative aspect of that is that their statistics are also forgotten. [seconds]

Default: 3600.0

## **dns\_max\_ttl**

How long the DNS lookups can be cached. If a DNS lookup returns several answers, pgbouncer will robin-between them in the meantime. Actual DNS TTL is ignored. [seconds]

Default: 15.0

## **dns\_nxdomain\_ttl**

How long error and NXDOMAIN DNS lookups can be cached. [seconds]

Default: 15.0

## **dns\_zone\_check\_period**

Period to check if zone serial has changed.

PgBouncer can collect dns zones from hostnames (everything after first dot) and then periodically check if zone serial changes. If it notices changes, all hostnames under that zone are looked up again. If any host ip changes, it's connections are invalidated.

Works only with UDNS backend ( --with-udns to configure).

Default: 0.0 (disabled)

## TLS settings

### client\_tls\_sslmode

TLS mode to use for connections from clients. TLS connections are disabled by default. When enabled, [client\\_tls\\_key\\_file](#) and [client\\_tls\\_cert\\_file](#) must be also configured to set up key and cert PgBouncer uses to accept client connections.

disable

Plain TCP. If client requests TLS, it's ignored. Default.

allow

If client requests TLS, it is used. If not, plain TCP is used. If client uses client-certificate, it is not validated.

prefer

Same as allow .

require

Client must use TLS. If not, client connection is rejected. If client uses client-certificate, it is not validated.

verify-ca

Client must use TLS with valid client certificate.

verify-full

Same as verify-ca .

### client\_tls\_key\_file

Private key for PgBouncer to accept client connections.

Default: not set.

### client\_tls\_cert\_file

Certificate for private key. Clients can validate it.

Default: not set.

### client\_tls\_ca\_file

Root certificate file to validate client certificates.

Default: unset.

### client\_tls\_protocols

Which TLS protocol versions are allowed. Allowed values: tlsv1.0 , tlsv1.1 , tlsv1.2 . Shortcuts: all (tlsv1.0,tlsv1.1,tlsv1.2), secure (tlsv1.2), legacy (all).

Default: all

### client\_tls\_ciphers

Default: fast

### client\_tls\_ecdhcurve

Elliptic Curve name to use for ECDH key exchanges.

Allowed values: none (DH is disabled), auto (256-bit ECDH), curve name.

Default: auto

### client\_tls\_dheparams

DHE key exchange type.

Allowed values: none (DH is disabled), auto (2048-bit DH), legacy (1024-bit DH).

Default: auto

## **server\_tls\_sslmode**

TLS mode to use for connections to PostgreSQL servers. TLS connections are disabled by default.

disable

Plain TCP. TCP is not even requested from server. Default.

allow

FIXME: if server rejects plain, try TLS?

prefer

TLS connection is always requested first from PostgreSQL, when refused connection will be established over plain TCP. Server certificate is not validated.

require

Connection must go over TLS. If server rejects it, plain TCP is not attempted. Server certificate is not validated.

verify-ca

Connection must go over TLS and server certificate must be valid according to [server\\_tls\\_ca\\_file](#). Server hostname is not checked against certificate.

verify-full

Connection must go over TLS and server certificate must be valid according to [server\\_tls\\_ca\\_file](#). Server hostname must match certificate info.

## **server\_tls\_ca\_file**

Root certificate file to validate PostgreSQL server certificates.

Default: unset.

## **server\_tls\_key\_file**

Private key for PgBouncer to authenticate against PostgreSQL server.

Default: not set.

## **server\_tls\_cert\_file**

Certificate for private key. PostgreSQL server can validate it.

Default: not set.

## **server\_tls\_protocols**

Which TLS protocol versions are allowed. Allowed values: tlsv1.0 , tlsv1.1 , tlsv1.2 . Shortcuts: all (tlsv1.0,tlsv1.1,tlsv1.2), secure (tlsv1.2), legacy (all).

Default: all

## **server\_tls\_ciphers**

Default: fast

# **Dangerous timeouts**

Setting following timeouts cause unexpected errors.

## **query\_timeout**

Queries running longer than that are canceled. This should be used only with slightly smaller server-side statement\_timeout, to apply only for network problems. [seconds]

Default: 0.0 (disabled)

## **query\_wait\_timeout**

Maximum time queries are allowed to spend waiting for execution. If the query is not assigned to a server during that time, the client is disconnected. This is used to prevent unresponsive servers from grabbing up connections. [seconds]

It also helps when server is down or database rejects connections for any reason. If this is disabled, clients will be queued infinitely.

Default: 120

### **client\_idle\_timeout**

Client connections idling longer than this many seconds are closed. This should be larger than the client-side connection lifetime settings, and only used for network problems. [seconds]

Default: 0.0 (disabled)

### **idle\_transaction\_timeout**

If client has been in "idle in transaction" state longer, it will be disconnected. [seconds]

Default: 0.0 (disabled)

## **Low-level network settings**

### **pkt\_buf**

Internal buffer size for packets. Affects size of TCP packets sent and general memory usage. Actual libpq packets can be larger than this so, no need to set it large.

Default: 4096

### **max\_packet\_size**

Maximum size for Postgres packets that PgBouncer allows through. One packet is either one query or one resultset row. Full resultset can be larger.

Default: 2147483647

### **listen\_backlog**

Backlog argument for listen(2). Determines how many new unanswered connection attempts are kept in queue. When queue is full, further new connections are dropped.

Default: 128

### **sbuf\_loopcnt**

How many times to process data on one connection, before proceeding. Without this limit, one connection with a big resultset can stall PgBouncer for a long time. One loop processes one [pkt\\_buf](#) amount of data. 0 means no limit.

Default: 5

### **suspend\_timeout**

How many seconds to wait for buffer flush during SUSPEND or reboot (-R). Connection is dropped if flush does not succeed.

Default: 10

### **tcp\_defer\_accept**

For details on this and other tcp options, please see `man 7 tcp`.

Default: 45 on Linux, otherwise 0

### **tcp\_socket\_buffer**

Default: not set

### **tcp\_keepalive**

Turns on basic keepalive with OS defaults.

On Linux, the system defaults are **tcp\_keepidle=7200** , **tcp\_keepintvl=75** , **tcp\_keepcnt=9** . They are probably similar on other OS-es.

Default: 1

### **tcp\_keepcnt**

Default: not set

### **tcp\_keepidle**

Default: not set

### **tcp\_keepintvl**

Default: not set

## **Section [databases]**

This contains key=value pairs where key will be taken as a database name and value as a libpq connect-string style list of key=value pairs. As actual libpq is not used, so not all features from libpq can be used (service=, .pgpass).

Database name can contain characters \_0-9A-Za-z without quoting. Names that contain other chars need to be quoted with standard SQL ident quoting: double quotes where "" is taken as single quote.

"\*" acts as fallback database: if the exact name does not exist, its value is taken as connect string for requested database. Such automatically created database entries are cleaned up if they stay idle longer then the time specified in [autodb\\_idle\\_timeout](#) parameter.

### **dbname**

Destination database name.

Default: same as client-side database name.

### **host**

Hostname or IP address to connect to. Hostnames are resolved on connect time, the result is cached per `dns_max_ttl` parameter. If DNS returns several results, they are used in round-robin manner.

Default: not set, meaning to use a Unix socket.

### **port**

Default: 5432

### **user, password**

If `user=` is set, all connections to the destination database will be done with the specified user, meaning that there will be only one pool for this database.

Otherwise PgBouncer tries to log into the destination database with client username, meaning that there will be one pool per user.

### **auth\_user**

If `auth_user` is set, any user not specified in `auth_file` will be queried from `pg_shadow` in the database using `auth_user` . `Auth_user`'s password will be taken from `auth_file` .

Direct access to `pg_shadow` requires admin rights. It's preferable to use non-admin user that calls `SECURITY DEFINER` function instead.

### **pool\_size**

Set maximum size of pools for this database. If not set, the `default_pool_size` is used.

## connect\_query

Query to be executed after a connection is established, but before allowing the connection to be used by any clients. If the query raises errors, they are logged but ignored otherwise.

## pool\_mode

Set the pool mode specific to this database. If not set, the default pool\_mode is used.

## max\_db\_connections

Configure a database-wide maximum (i.e. all pools within the database will not have more than this many server connections).

## client\_encoding

Ask specific client\_encoding from server.

## datestyle

Ask specific datestyle from server.

## timezone

Ask specific **timezone** from server.

## Section [users]

This contains key=value pairs where key will be taken as a user name and value as a libpq connect-string style list of key=value pairs. As actual libpq is not used, so not all features from libpq can be used.

## pool\_mode

Set the pool mode to be used for all connections from this user. If not set, the database or default pool\_mode is used.

## Include directive

The PgBouncer config file can contain include directives, which specify another config file to read and process. This allows for splitting the configuration file into physically separate parts. The include directives look like this:

```
%include filename
```

If the file name is not absolute path it is taken as relative to current working directory.

## Authentication file format

PgBouncer needs its own user database. The users are loaded from a text file in following format:

```
"username1" "password" ...  
"username2" "md5abcdef012342345" ...
```

There should be at least 2 fields, surrounded by double quotes. The first field is the username and the second is either a plain-text or a MD5-hidden password. PgBouncer ignores the rest of the line.

This file format is equivalent to text files used by PostgreSQL 8.x for authentication info, thus allowing PgBouncer to work directly on PostgreSQL authentication files in data directory.

Since PostgreSQL 9.0, the text files are not used anymore. Thus the auth file needs to be generated. See *./etc/mkauth.py* for sample script to generate auth file from *pg\_shadow* table.

PostgreSQL MD5-hidden password format:

```
"md5" + md5(password + username)
```

So user *admin* with password *1234* will have MD5-hidden password *md545f2603610af569b6155c45067268c6b* .

# HBA file format

It follows the format of PostgreSQL pg\_hba.conf file - <http://www.postgresql.org/docs/9.4/static/auth-pg-hba-conf.html>

There are following differences:

- Supported record types: *local* , *host* , *hostssl* , *hostnossl* .
- Database field: Supports *all* , *sameuser* , *@file* , multiple names. Not supported: *replication* , *samerole* , *samegroup* .
- Username field: Supports *all* , *@file* , multiple names. Not supported: *+groupname* .
- Address field: Supported IPv4, IPv6. Not supported: DNS names, domain prefixes.
- Auth-method field: Supported methods: *trust* , *reject* , *md5* , *password* , *peer* , *cert* . Not supported: *gss* , *sspi* , *ident* , *ldap* , *radius* , *pam* . Also username map ( *map=* ) parameter is not supported.

## Example

Minimal config:

```
[databases]
template1 = host=127.0.0.1 dbname=template1 auth_user=someuser
```

```
[pgbouncer]
pool_mode = session
listen_port = 6543
listen_addr = 127.0.0.1
auth_type = md5
auth_file = users.txt
logfile = pgbouncer.log
pidfile = pgbouncer.pid
admin_users = someuser
stats_users = stat_collector
```

Database defaults:

```
[databases]

; foodb over unix socket
foodb =

; redirect bardb to bazdb on localhost
bardb = host=127.0.0.1 dbname=bazdb

; access to destination database will go with single user
forcedb = host=127.0.0.1 port=300 user=baz password=foo client_encoding=UNICODE datestyle=ISO
```

Example of secure function for auth\_query:

```
CREATE OR REPLACE FUNCTION pgbouncer.user_lookup(in i_username text, out uname text, out phash text)
RETURNS record AS $$
BEGIN
    SELECT username, passwd FROM pg_catalog.pg_shadow
    WHERE username = i_username INTO uname, phash;
    RETURN;
END;
$$ LANGUAGE plpgsql SECURITY DEFINER;
REVOKE ALL ON FUNCTION pgbouncer.user_lookup(text) FROM public, pgbouncer;
GRANT EXECUTE ON FUNCTION pgbouncer.user_lookup(text) TO pgbouncer;
```

--- title: "PgBouncer TODO list" draft: false ---

## Highly visible missing features

Significant amount of users feel the need for those.

- Protocol-level plan cache.
- LISTEN/NOTIFY. Requires strict SQL format.

Waiting for contributors...

## Problems / cleanups

- Bad naming in data structures: \* PgSocket->auth\_user [vs. PgDatabase->auth\_user] \* PgSocket->db [vs. PgPool->db]
- other per-user settings
- Maintenance order vs. lifetime\_kill\_gap: <http://lists.pgfoundry.org/pipermail/pgbouncer-general/2011-February/000679.html>
- per\_loop\_maint/per\_loop\_activate take too much time in case of moderate load and lots of pools. Perhaps active\_pool\_list would help, which contains only pools touched in current loop.
- new states for clients: idle and in-query. That allows to apply client\_idle\_timeout and query\_timeout without walking all clients on maintenance time.
- check if SQL error codes are correct
- removing user should work - kill connections
- keep stats about error counts
- cleanup of logging levels, to make log more useful
- to test: - signal flood - no mem / no fds handling
- fix high-freq maintenance timer - it's only needed when PAUSE/RESUME/shutdown is issued.
- Get rid of SBUF\_SMALL\_PKT logic - it makes processing code complex. Needs a new sbuf\_prepare\_\*() to notify sbuf about short data. [Plain 'false' from handler postpones processing to next event loop.]
- units for config parameters.

## Dubious/complicated features

- Load-balancing / failover. Both are already solved via DNS. Adding load-balancing config in pgbouncer might be good idea. Adding failover decision-making is not...
- User-based route. Simplest would be to move db info to pool and fill username into dns.
- some preliminary notification that fd limit is full
- Move all "look-at-full-packet" situations to SBUF\_EV\_PKT\_CALLBACK
- *pool\_mode = plproxy* - use postgres in full-duplex mode for autocommit queries, multiplexing several queries into one connection. Should result in more efficient CPU usage of server.
- SMP: spread sockets over per-cpu threads. Needs confirmation that single-threadedness can be problem. It can also be that only accept() + login handling of short connection is problem that could be solved by just having threads for login handling, which would be lot simpler or just deciding that it is not worth fixing.
