

PostGIS 2.3.8 Manual

Contents

1	Introduction	1
1.1	Project Steering Committee	1
1.2	Core Contributors Present	1
1.3	Core Contributors Past	2
1.4	Other Contributors	2
1.5	More Information	3
2	PostGIS Installation	4
2.1	Short Version	4
2.2	Install Requirements	5
2.3	Getting the Source	7
2.4	Compiling and Install from Source: Detailed	7
2.4.1	Configuration	7
2.4.2	Building	9
2.4.3	Building PostGIS Extensions and Deploying them	9
2.4.4	Testing	11
2.4.5	Installation	20
2.5	Creating a spatial database using EXTENSIONS	21
2.6	Create a spatially-enabled database without using extensions	21
2.7	Installing and Using the address standardizer	22
2.7.1	Installing Regex::Assemble	23
2.8	Installing, Upgrading Tiger Geocoder and loading data	23
2.8.1	Tiger Geocoder Enabling your PostGIS database: Using Extension	23
2.8.1.1	Converting a Tiger Geocoder Regular Install to Extension Model	25
2.8.2	Tiger Geocoder Enabling your PostGIS database: Not Using Extensions	25
2.8.3	Using Address Standardizer Extension with Tiger geocoder	26
2.8.4	Loading Tiger Data	26
2.8.5	Upgrading your Tiger Geocoder Install	27
2.9	Create a spatially-enabled database from a template	28
2.10	Upgrading	28

2.10.1	Soft upgrade	28
2.10.1.1	Soft Upgrade Pre 9.1+ or without extensions	28
2.10.1.2	Soft Upgrade 9.1+ using extensions	29
2.10.2	Hard upgrade	29
2.11	Common Problems during installation	30
2.12	Loader/Dumper	31
3	PostGIS Frequently Asked Questions	32
4	Using PostGIS: Data Management and Queries	36
4.1	GIS Objects	36
4.1.1	OpenGIS WKB and WKT	36
4.1.2	PostGIS EWKB, EWKT and Canonical Forms	37
4.1.3	SQL-MM Part 3	38
4.2	PostGIS Geography Type	38
4.2.1	Geography Basics	39
4.2.2	When to use Geography Data type over Geometry data type	40
4.2.3	Geography Advanced FAQ	41
4.3	Using OpenGIS Standards	41
4.3.1	The SPATIAL_REF_SYS Table and Spatial Reference Systems	42
4.3.2	The GEOMETRY_COLUMNS VIEW	43
4.3.3	Creating a Spatial Table	43
4.3.4	Manually Registering Geometry Columns in geometry_columns	44
4.3.5	Ensuring OpenGIS compliancy of geometries	47
4.3.6	Dimensionally Extended 9 Intersection Model (DE-9IM)	51
4.3.6.1	Theory	52
4.4	Loading GIS (Vector) Data	55
4.4.1	Loading Data Using SQL	55
4.4.2	shp2pgsql: Using the ESRI Shapefile Loader	55
4.5	Retrieving GIS Data	57
4.5.1	Using SQL to Retrieve Data	57
4.5.2	Using the Dumper	58
4.6	Building Indexes	58
4.6.1	GiST Indexes	59
4.6.2	BRIN Indexes	59
4.6.3	Using Indexes	60
4.7	Complex Queries	61
4.7.1	Taking Advantage of Indexes	61
4.7.2	Examples of Spatial SQL	61

5	Raster Data Management, Queries, and Applications	65
5.1	Loading and Creating Rasters	65
5.1.1	Using raster2pgsql to load rasters	65
5.1.2	Creating rasters using PostGIS raster functions	69
5.2	Raster Catalogs	69
5.2.1	Raster Columns Catalog	70
5.2.2	Raster Overviews	71
5.3	Building Custom Applications with PostGIS Raster	71
5.3.1	PHP Example Outputting using ST_AsPNG in concert with other raster functions	72
5.3.2	ASP.NET C# Example Outputting using ST_AsPNG in concert with other raster functions	72
5.3.3	Java console app that outputs raster query as Image file	74
5.3.4	Use PLPython to dump out images via SQL	75
5.3.5	Outputting Rasters with PSQL	76
6	Using PostGIS Geometry: Building Applications	77
6.1	Using MapServer	77
6.1.1	Basic Usage	77
6.1.2	Frequently Asked Questions	78
6.1.3	Advanced Usage	79
6.1.4	Examples	80
6.2	Java Clients (JDBC)	81
6.3	C Clients (libpq)	82
6.3.1	Text Cursors	82
6.3.2	Binary Cursors	82
7	Performance tips	83
7.1	Small tables of large geometries	83
7.1.1	Problem description	83
7.1.2	Workarounds	83
7.2	CLUSTERing on geometry indices	84
7.3	Avoiding dimension conversion	84
7.4	Tuning your configuration	85
7.4.1	Startup	85
7.4.2	Runtime	85

8	PostGIS Reference	87
8.1	PostgreSQL PostGIS Geometry/Geography/Box Types	87
8.1.1	box2d	87
8.1.2	box3d	87
8.1.3	geometry	88
8.1.4	geometry_dump	88
8.1.5	geography	88
8.2	PostGIS Grand Unified Custom Variables (GUCs)	89
8.2.1	postgis.backend	89
8.2.2	postgis.gdal_datapath	89
8.2.3	postgis.gdal_enabled_drivers	90
8.2.4	postgis.enable_outdb_rasters	92
8.3	Management Functions	92
8.3.1	AddGeometryColumn	92
8.3.2	DropGeometryColumn	94
8.3.3	DropGeometryTable	95
8.3.4	PostGIS_Full_Version	96
8.3.5	PostGIS_GEOS_Version	96
8.3.6	PostGIS_LibXML_Version	97
8.3.7	PostGIS_Lib_Build_Date	97
8.3.8	PostGIS_Lib_Version	98
8.3.9	PostGIS_PROJ_Version	98
8.3.10	PostGIS_Scripts_Build_Date	99
8.3.11	PostGIS_Scripts_Installed	99
8.3.12	PostGIS_Scripts_Released	100
8.3.13	PostGIS_Version	100
8.3.14	Populate_Geometry_Columns	101
8.3.15	UpdateGeometrySRID	102
8.4	Geometry Constructors	103
8.4.1	ST_BdPolyFromText	103
8.4.2	ST_BdMPolyFromText	104
8.4.3	ST_Box2dFromGeoHash	105
8.4.4	ST_GeogFromText	105
8.4.5	ST_GeographyFromText	106
8.4.6	ST_GeogFromWKB	106
8.4.7	ST_GeomFromTWKB	107
8.4.8	ST_GeomCollFromText	108
8.4.9	ST_GeomFromEWKB	108
8.4.10	ST_GeomFromEWKT	110

8.4.11	ST_GeometryFromText	111
8.4.12	ST_GeomFromGeoHash	111
8.4.13	ST_GeomFromGML	112
8.4.14	ST_GeomFromGeoJSON	115
8.4.15	ST_GeomFromKML	116
8.4.16	ST_GMLToSQL	116
8.4.17	ST_GeomFromText	117
8.4.18	ST_GeomFromWKB	118
8.4.19	ST_LineFromEncodedPolyline	119
8.4.20	ST_LineFromMultiPoint	120
8.4.21	ST_LineFromText	120
8.4.22	ST_LineFromWKB	121
8.4.23	ST_LinestringFromWKB	122
8.4.24	ST_MakeBox2D	123
8.4.25	ST_3DMakeBox	124
8.4.26	ST_MakeLine	124
8.4.27	ST_MakeEnvelope	126
8.4.28	ST_MakePolygon	126
8.4.29	ST_MakePoint	128
8.4.30	ST_MakePointM	129
8.4.31	ST_MLineFromText	130
8.4.32	ST_MPointFromText	131
8.4.33	ST_MPolyFromText	132
8.4.34	ST_Point	133
8.4.35	ST_PointFromGeoHash	133
8.4.36	ST_PointFromText	134
8.4.37	ST_PointFromWKB	135
8.4.38	ST_Polygon	136
8.4.39	ST_PolygonFromText	137
8.4.40	ST_WKBToSQL	138
8.4.41	ST_WKTToSQL	138
8.5	Geometry Accessors	139
8.5.1	GeometryType	139
8.5.2	ST_Boundary	140
8.5.3	ST_CoordDim	143
8.5.4	ST_Dimension	143
8.5.5	ST_EndPoint	144
8.5.6	ST_Envelope	145
8.5.7	ST_BoundingDiagonal	146

8.5.8	ST_ExteriorRing	147
8.5.9	ST_GeometryN	148
8.5.10	ST_GeometryType	150
8.5.11	ST_InteriorRingN	151
8.5.12	ST_IsClosed	152
8.5.13	ST_IsCollection	154
8.5.14	ST_IsEmpty	155
8.5.15	ST_IsRing	156
8.5.16	ST_IsSimple	157
8.5.17	ST_IsValid	158
8.5.18	ST_IsValidReason	159
8.5.19	ST_IsValidDetail	160

Abstract

PostGIS is an extension to the PostgreSQL object-relational database system which allows GIS (Geographic Information Systems) objects to be stored in the database. PostGIS includes support for GiST-based R-Tree spatial indexes, and functions for analysis and processing of GIS objects.

This is the manual for version 2.3.8

Feel free to use this material any way you like, but we ask that you attribute credit to the PostGIS Project and wherever possible, a link back to <http://postgis.net>.

Chapter 1

Introduction

PostGIS was developed by Refrations Research Inc, as a spatial database technology research project. Refrations is a GIS and database consulting company in Victoria, British Columbia, Canada, specializing in data integration and custom software development. We plan on supporting and developing PostGIS to support a range of important GIS functionality, including full OpenGIS support, advanced topological constructs (coverages, surfaces, networks), desktop user interface tools for viewing and editing GIS data, and web-based access tools.

PostGIS is an incubation project of the OSGeo Foundation. PostGIS is being continually improved and funded by many FOSS4G Developers as well as corporations all over the world that gain great benefit from its functionality and versatility.

1.1 Project Steering Committee

The PostGIS Project Steering Committee (PSC) coordinates the general direction, release cycles, documentation, and outreach efforts for the PostGIS project. In addition the PSC provides general user support, accepts and approves patches from the general PostGIS community and votes on miscellaneous issues involving PostGIS such as developer commit access, new PSC members or significant API changes.

Mark Cave-Ayland Coordinates bug fixing and maintenance effort, alignment of PostGIS with PostgreSQL releases, spatial index selectivity and binding, loader/dumper, and Shapefile GUI Loader, integration of new and new function enhancements.

Regina Obe Buildbot Maintenance, windows production and experimental builds, Documentation, general user support on PostGIS newsgroup, X3D support, Tiger Geocoder Support, management functions, and smoke testing new functionality or major code changes.

Bborie Park Raster development, integration with GDAL, raster loader, user support, general bug fixing, testing on various OS (Slackware, Mac, Windows, and more)

Paul Ramsey (Chair) Co-founder of PostGIS project. General bug fixing, geography support, geography and geometry index support (2D, 3D, nD index and anything spatial index), underlying geometry internal structures, PointCloud (in development), GEOS functionality integration and alignment with GEOS releases, loader/dumper, and Shapefile GUI loader.

Sandro Santilli Bug fixes and maintenance and integration of new GEOS functionality and alignment with GEOS releases, Topology support, and Raster framework and low level api functions.

1.2 Core Contributors Present

Jorge Arévalo Raster development, GDAL driver support, loader

Nicklas Avén Distance function enhancements (including 3D distance and relationship functions) and additions, Tiny WKB output format (TWKB) (in development) and general user support

Dan Baston Geometry clustering function additions, other geometry algorithm enhancements, and general user support

Olivier Courtin Input output XML (KML,GML)/GeoJSON functions, 3D support and bug fixes.

Mateusz Loskot CMake support for PostGIS, built original raster loader in python and low level raster api functions

Pierre Racine Raster overall architecture, prototyping, programming support

David Zwarg Raster development (mostly map algebra analytic functions)

1.3 Core Contributors Past

Chris Hodgson Prior PSC Member. General development, site and buildbot maintenance, OSGeo incubation management

Kevin Neufeld Prior PSC Member. Documentation and documentation support tools, buildbot maintenance, advanced user support on PostGIS newsgroup, and PostGIS maintenance function enhancements.

Dave Blasby The original developer/Co-founder of PostGIS. Dave wrote the server side objects, index bindings, and many of the server side analytical functions.

Jeff Lounsbury Original development of the Shape file loader/dumper. Current PostGIS Project Owner representative.

Mark Leslie Ongoing maintenance and development of core functions. Enhanced curve support. Shapefile GUI loader.

1.4 Other Contributors

Individual Contributors In alphabetical order: Alex Bodnaru, Alex Mayrhofer, Andrea Peri, Andreas Forø Tollefsen, Andreas Neumann, Anne Ghisla, Barbara Phillipot, Ben Jubb, Bernhard Reiter, Brian Hamlin, Bruce Rindahl, Bruno Wolff III, Bryce L. Nordgren, Carl Anderson, Charlie Savage, Dane Springmeyer, David Skea, David Techer, Eduin Carrillo, Even Rouault, Frank Warmerdam, George Silva, Gerald Fenoy, Gino Lucrezi, Guillaume Lelarge, IIDA Tetsushi, Ingvild Nystuen, Jason Smith, Jeff Adams, Jose Carlos Martinez Llari, Julien Rouhaud, Kashif Rasul, Klaus Foerster, Kris Jurka, Leo Hsu, Loic Dachary, Luca S. Percich, Maria Arias de Reyna, Mark Sondheim, Markus Schaber, Maxime Guillaud, Maxime van Noppen, Michael Fuhr, Mike Toews, Nathan Wagner, Nathaniel Clay, Nikita Shulga, Norman Vine, Rafal Magda, Ralph Mason, Rémi Cura, Richard Greenwood, Silvio Grosso, Steffen Macke, Stephen Frost, Tom van Tilburg, Vincent Mora, Vincent Picavet

Corporate Sponsors These are corporate entities that have contributed developer time, hosting, or direct monetary funding to the PostGIS project

In alphabetical order: Arrival 3D, Associazione Italiana per l'Informazione Geografica Libera (GFOSS.it), AusVet, Avenia, Azavea, Cadcorp, CampToCamp, CartoDB, City of Boston (DND), Clever Elephant Solutions, Cooperativa Alveo, Deimos Space, Faunalia, Geographic Data BC, Hunter Systems Group, Lidwala Consulting Engineers, LisaSoft, Logical Tracking & Tracing International AG, Maponics, Michigan Tech Research Institute, Natural Resources Canada, Norwegian Forest and Landscape Institute, Boundless (former OpenGeo), OSGeo, Oslandia, Palantir Technologies, Paragon Corporation, R3 GIS, Refrations Research, Regione Toscana - SITA, Safe Software, Sirius Corporation plc, Stadt Uster, UC Davis Center for Vectorborne Diseases, University of Laval, U.S Department of State (HIU), Zonar Systems

Crowd Funding Campaigns Crowd funding campaigns are campaigns we run to get badly wanted features funded that can service a large number of people. Each campaign is specifically focused on a particular feature or set of features. Each sponsor chips in a small fraction of the needed funding and with enough people/organizations contributing, we have the funds to pay for the work that will help many. If you have an idea for a feature you think many others would be willing to co-fund, please post to the [PostGIS newsgroup](#) your thoughts and together we can make it happen.

PostGIS 2.0.0 was the first release we tried this strategy. We used [PledgeBank](#) and we got two successful campaigns out of it.

[postgistology](#) - 10 plus sponsors each contributed \$250 USD to build toTopoGeometry function and beef up topology support in 2.0.0. It happened.

postgis64windows - 20 someodd sponsors each contributed \$100 USD to pay for the work needed to work out PostGIS 64-bit issues on windows. It happened. We now have a 64-bit release for PostGIS 2.0.1 available on PostgreSQL stack builder.

Important Support Libraries The **GEOS** geometry operations library, and the algorithmic work of Martin Davis in making it all work, ongoing maintenance and support of Mateusz Loskot, Sandro Santilli (strk), Paul Ramsey and others.

The **GDAL** Geospatial Data Abstraction Library, by Frank Warmerdam and others is used to power much of the raster functionality introduced in PostGIS 2.0.0. In kind, improvements needed in GDAL to support PostGIS are contributed back to the GDAL project.

The **Proj4** cartographic projection library, and the work of Gerald Evenden and Frank Warmerdam in creating and maintaining it.

Last but not least, the **PostgreSQL DBMS**, The giant that PostGIS stands on. Much of the speed and flexibility of PostGIS would not be possible without the extensibility, great query planner, GIST index, and plethora of SQL features provided by PostgreSQL.

1.5 More Information

- The latest software, documentation and news items are available at the PostGIS web site, <http://postgis.net>.
- More information about the GEOS geometry operations library is available at <http://trac.osgeo.org/geos/>.
- More information about the Proj4 reprojection library is available at <http://trac.osgeo.org/proj/>.
- More information about the PostgreSQL database server is available at the PostgreSQL main site <http://www.postgresql.org>.
- More information about GiST indexing is available at the PostgreSQL GiST development site, <http://www.sai.msu.su/~megeera/postgres/gist/>.
- More information about MapServer internet map server is available at <http://mapserver.org>.
- The "**Simple Features for Specification for SQL**" is available at the OpenGIS Consortium web site: <http://www.opengeospatial.org/>.

Chapter 2

PostGIS Installation

This chapter details the steps required to install PostGIS.

2.1 Short Version

To compile assuming you have all the dependencies in your search path:

```
tar xvfz postgis-2.3.8.tar.gz
cd postgis-2.3.8
./configure
make
make install
```

Once postgis is installed, it needs to be enabled in each individual database you want to use it in.

**Note**

The raster support is currently optional, but installed by default. For enabling using the PostgreSQL 9.1+ extensions model raster is required. Using the extension enable process is preferred and more user-friendly. To spatially enable your database:

```
psql -d yourdatabase -c "CREATE EXTENSION postgis;"
psql -d yourdatabase -c "CREATE EXTENSION postgis_topology;"
-- if you built with sfcgal support --
psql -d yourdatabase -c "CREATE EXTENSION postgis_sfcgal;"

-- if you want to install tiger geocoder --
psql -d yourdatabase -c "CREATE EXTENSION fuzzystrmatch"
psql -d yourdatabase -c "CREATE EXTENSION postgis_tiger_geocoder;"

-- if you installed with pcre
-- you should have address_standardizer extension as well
psql -d yourdatabase -c "CREATE EXTENSION address_standardizer;"
```

Please refer to Section 2.4.3 for more details about querying installed/available extensions and upgrading extensions, or switching from a non-extension install to an extension install.

For those running who decided for some reason not to compile with raster support, or just are old-fashioned, here are longer more painful instructions for you:

All the .sql files once installed will be installed in share/contrib/postgis-2.2 folder of your PostgreSQL install

```
createdb yourdatabase
createlang plpgsql yourdatabase
psql -d yourdatabase -f postgis.sql
psql -d yourdatabase -f postgis_comments.sql
psql -d yourdatabase -f spatial_ref_sys.sql
psql -d yourdatabase -f topology.sql
psql -d yourdatabase -f topology_comments.sql

-- only if you compiled with raster (GDAL)
psql -d yourdatabase -f rtpostgis.sql
psql -d yourdatabase -f raster_comments.sql

--if you built with sfcgal support --
psql -d yourdatabase -f sfcgal.sql
psql -d yourdatabase -f sfcgal_comments.sql
```

The rest of this chapter goes into detail each of the above installation steps.

As of PostGIS 2.1.3, out-of-db rasters and all raster drivers are disabled by default. In order to re-enable these, you need to set the following environment variables `POSTGIS_GDAL_ENABLED_DRIVERS` and `POSTGIS_ENABLE_OUTDB_RASTERS` in the server environment. For PostGIS 2.2, you can use the more cross-platform approach of setting the corresponding Section 8.2.

If you want to enable offline raster:

```
POSTGIS_ENABLE_OUTDB_RASTERS=1
```

Any other setting or no setting at all will disable out of db rasters.

In order to enable all GDAL drivers available in your GDAL install, set this environment variable as follows

```
POSTGIS_GDAL_ENABLED_DRIVERS=ENABLE_ALL
```

If you want to only enable specific drivers, set your environment variable as follows:

```
POSTGIS_GDAL_ENABLED_DRIVERS="GTiff PNG JPEG GIF XYZ"
```

**Note**

If you are on windows, do not quote the driver list

Setting environment variables varies depending on OS. For PostgreSQL installed on Ubuntu or Debian via `apt-postgresql`, the preferred way is to edit `/etc/postgresql/9.3/main/environment` where 9.3 refers to version of PostgreSQL and main refers to the cluster.

On windows, if you are running as a service, you can set via System variables which for Windows 7 you can get to by right-clicking on Computer->Properties Advanced System Settings or in explorer navigating to Control Panel\All Control Panel Items\System. Then clicking *Advanced System Settings ->Advanced->Environment Variables* and adding new system variables.

After you set the environment variables, you'll need to restart your PostgreSQL service for the changes to take effect.

2.2 Install Requirements

PostGIS has the following requirements for building and usage:

Required

- PostgreSQL 9.2 and \leq PostgreSQL 9.6. A complete installation of PostgreSQL (including server headers) is required. PostgreSQL is available from <http://www.postgresql.org> .
For a full PostgreSQL / PostGIS support matrix and PostGIS/GEOS support matrix refer to <http://trac.osgeo.org/postgis/wiki/UsersWikiPostgreSQLPostGIS>
- GNU C compiler (`gcc`). Some other ANSI C compilers can be used to compile PostGIS, but we find far fewer problems when compiling with `gcc`.
- GNU Make (`gmake` or `make`). For many systems, GNU `make` is the default version of `make`. Check the version by invoking `make -v`. Other versions of `make` may not process the PostGIS `Makefile` properly.
- Proj4 reprojection library, version 4.6.0 or greater. The Proj4 library is used to provide coordinate reprojection support within PostGIS. Proj4 is available for download from <http://trac.osgeo.org/proj/> .
- GEOS geometry library, version 3.3 or greater, but GEOS 3.5+ is recommended to take full advantage of all the new functions and features. Without GEOS 3.5, you will be missing some major enhancements such as `ST_ClipByBox2D` and `ST_Subdivide`. GEOS is available for download from <http://trac.osgeo.org/geos/> and 3.4+ is backward-compatible with older versions so fairly safe to upgrade.
- LibXML2, version 2.5.x or higher. LibXML2 is currently used in some imports functions (`ST_GeomFromGML` and `ST_GeomFromKML`). LibXML2 is available for download from <http://xmlsoft.org/downloads.html>.
- JSON-C, version 0.9 or higher. JSON-C is currently used to import GeoJSON via the function `ST_GeomFromGeoJson`. JSON-C is available for download from <https://github.com/json-c/json-c/releases/>.
- GDAL, version 1.8 or higher (1.9 or higher is strongly recommended since some things will not work well or behavior differently with lower versions). This is required for raster support and to be able to install with `CREATE EXTENSION postgis` so highly recommended for those running 9.1+. <http://trac.osgeo.org/gdal/wiki/DownloadSource>.

Optional

- GDAL (pseudo optional) only if you don't want raster and don't care about installing with `CREATE EXTENSION postgis` can you leave it out. Keep in mind other extensions may have a `requires postgis` extension which will prevent you from installing them unless you install `postgis` as an extension. So it is highly recommended you compile with GDAL support.
Also make sure to enable the drivers you want to use as described in Section 2.1.
- GTK (requires GTK+2.0, 2.8+) to compile the `shp2pgsql-gui` shape file loader. <http://www.gtk.org/> .
- SFCGAL, version 1.1 (or higher) could be used to provide additional 2D and 3D advanced analysis functions to PostGIS cf Section 8.10. And also allow to use SFCGAL rather than GEOS for some 2D functions provided by both backends (like `ST_Intersection` or `ST_Area`, for instance). A PostgreSQL configuration variable `postgis.backend` allow end user to control which backend he want to use if SFCGAL is installed (GEOS by default). Nota: SFCGAL 1.2 require at least CGAL 4.3 and Boost 1.54 (cf: <http://oslandia.github.io/SFCGAL/installation.html>) <https://github.com/Oslandia/SFCGAL>.
- In order to build the Chapter 12 you will also need PCRE <http://www.pcre.org> (which generally is already installed on nix systems). `Regex::Assemble` perl CPAN package is only needed if you want to rebuild the data encoded in `parseaddress-stcity`. Chapter 12 will automatically be built if it detects a PCRE library, or you pass in a valid `--with-pcre-dir=/path/to/pcre` during configure.
- CUnit (CUnit). This is needed for regression testing. <http://cunit.sourceforge.net/>
- DocBook (`xsltproc`) is required for building the documentation. Docbook is available from <http://www.docbook.org/> .
- DBLatex (`dblatex`) is required for building the documentation in PDF format. DBLatex is available from <http://dblatex.sourceforge.net/> .
- ImageMagick (`convert`) is required to generate the images used in the documentation. ImageMagick is available from <http://www.imagemagick.org/> .

2.3 Getting the Source

Retrieve the PostGIS source archive from the downloads website <http://download.osgeo.org/postgis/source/postgis-2.3.8.tar.gz>

```
wget http://download.osgeo.org/postgis/source/postgis-2.3.8.tar.gz
tar -xvzf postgis-2.3.8.tar.gz
```

This will create a directory called `postgis-2.3.8` in the current working directory.

Alternatively, checkout the source from the `svn` repository <http://svn.osgeo.org/postgis/trunk/> .

```
svn checkout http://svn.osgeo.org/postgis/trunk/ postgis-2.3.8
```

Change into the newly created `postgis-2.3.8` directory to continue the installation.

2.4 Compiling and Install from Source: Detailed

Note

Many OS systems now include pre-built packages for PostgreSQL/PostGIS. In many cases compilation is only necessary if you want the most bleeding edge versions or you are a package maintainer.

A small yellow sticky note icon with the word "Note!" written on it in black text.

This section includes general compilation instructions, if you are compiling for Windows etc or another OS, you may find additional more detailed help at [PostGIS User contributed compile guides](#) and [PostGIS Dev Wiki](#).

Pre-Built Packages for various OS are listed in [PostGIS Pre-built Packages](#)

If you are a windows user, you can get stable builds via Stackbuilder or [PostGIS Windows download site](#) We also have [very bleeding-edge windows experimental builds](#) that are built usually once or twice a week or whenever anything exciting happens. You can use these to experiment with the in progress releases of PostGIS

The PostGIS module is an extension to the PostgreSQL backend server. As such, PostGIS 2.3.8 *requires* full PostgreSQL server headers access in order to compile. It can be built against PostgreSQL versions 9.2 or higher. Earlier versions of PostgreSQL are *not* supported.

Refer to the PostgreSQL installation guides if you haven't already installed PostgreSQL. <http://www.postgresql.org> .

Note

For GEOS functionality, when you install PostgreSQL you may need to explicitly link PostgreSQL against the standard C++ library:

A small yellow sticky note icon with the word "Note!" written on it in black text.

```
LDFLAGS=-lstdc++ ./configure [YOUR OPTIONS HERE]
```

This is a workaround for bogus C++ exceptions interaction with older development tools. If you experience weird problems (backend unexpectedly closed or similar things) try this trick. This will require recompiling your PostgreSQL from scratch, of course.

The following steps outline the configuration and compilation of the PostGIS source. They are written for Linux users and will not work on Windows or Mac.

2.4.1 Configuration

As with most linux installations, the first step is to generate the Makefile that will be used to build the source code. This is done by running the shell script

`./configure`

With no additional parameters, this command will attempt to automatically locate the required components and libraries needed to build the PostGIS source code on your system. Although this is the most common usage of `./configure`, the script accepts several parameters for those who have the required libraries and programs in non-standard locations.

The following list shows only the most commonly used parameters. For a complete list, use the `--help` or `--help=short` parameters.

--prefix=PREFIX This is the location the PostGIS libraries and SQL scripts will be installed to. By default, this location is the same as the detected PostgreSQL installation.

Caution

This parameter is currently broken, as the package will only install into the PostgreSQL installation directory. Visit <http://trac.osgeo.org/postgis/ticket/635> to track this bug.

--with-pgconfig=FILE PostgreSQL provides a utility called `pg_config` to enable extensions like PostGIS to locate the PostgreSQL installation directory. Use this parameter (**--with-pgconfig=/path/to/pg_config**) to manually specify a particular PostgreSQL installation that PostGIS will build against.

--with-gdalconfig=FILE GDAL, a required library, provides functionality needed for raster support `gdal-config` to enable software installations to locate the GDAL installation directory. Use this parameter (**--with-gdalconfig=/path/to/gdal-config**) to manually specify a particular GDAL installation that PostGIS will build against.

--with-geosconfig=FILE GEOS, a required geometry library, provides a utility called `geos-config` to enable software installations to locate the GEOS installation directory. Use this parameter (**--with-geosconfig=/path/to/geos-config**) to manually specify a particular GEOS installation that PostGIS will build against.

--with-xml2config=FILE LibXML is the library required for doing `GeomFromKML/GML` processes. It normally is found if you have `libxml` installed, but if not or you want a specific version used, you'll need to point PostGIS at a specific `xml2-config` `confi` file to enable software installations to locate the LibXML installation directory. Use this parameter (**>--with-xml2config=/path/to/xml2-config**) to manually specify a particular LibXML installation that PostGIS will build against.

--with-projdir=DIR Proj4 is a reprojection library required by PostGIS. Use this parameter (**--with-projdir=/path/to/projdir**) to manually specify a particular Proj4 installation directory that PostGIS will build against.

--with-libiconv=DIR Directory where `iconv` is installed.

--with-jsondir=DIR **JSON-C** is an MIT-licensed JSON library required by PostGIS `ST_GeomFromJSON` support. Use this parameter (**--with-jsondir=/path/to/jsondir**) to manually specify a particular JSON-C installation directory that PostGIS will build against.

--with-pcredir=DIR **PCRE** is an BSD-licensed Perl Compatible Regular Expression library required by `address_standardizer` extension. Use this parameter (**--with-pcredir=/path/to/pcredir**) to manually specify a particular PCRE installation directory that PostGIS will build against.

--with-gui Compile the data import GUI (requires `GTK+2.0`). This will create `shp2pgsql-gui` graphical interface to `shp2pgsql`.

--with-raster Compile with raster support. This will build `rtpostgis-2.3.8` library and `rtpostgis.sql` file. This may not be required in final release as plan is to build in raster support by default.

--with-topology Compile with topology support. This will build the `topology.sql` file. There is no corresponding library as all logic needed for topology is in `postgis-2.3.8` library.

--with-gettext=no By default PostGIS will try to detect `gettext` support and compile with it, however if you run into incompatibility issues that cause breakage of loader, you can disable it entirely with this command. Refer to ticket <http://trac.osgeo.org/postgis/ticket/748> for an example issue solved by configuring with this. NOTE: that you aren't missing much by turning this off. This is used for international help/label support for the GUI loader which is not yet documented and still experimental.

--with-sfcgal=PATH By default PostGIS will not install with sfcgal support without this switch. `PATH` is an optional argument that allows to specify an alternate `PATH` to `sfcgal-config`.

Note

If you obtained PostGIS from the SVN [repository](#) , the first step is really to run the script

./autogen.sh

This script will generate the **configure** script that in turn is used to customize the installation of PostGIS.

If you instead obtained PostGIS as a tarball, running **./autogen.sh** is not necessary as **configure** has already been generated.

2.4.2 Building

Once the Makefile has been generated, building PostGIS is as simple as running

make

The last line of the output should be "PostGIS was built successfully. Ready to install."

As of PostGIS v1.4.0, all the functions have comments generated from the documentation. If you wish to install these comments into your spatial databases later, run the command which requires docbook. The `postgis_comments.sql` and other package comments files `raster_comments.sql`, `topology_comments.sql` are also packaged in the tar.gz distribution in the `doc` folder so no need to make comments if installing from the tar ball.

make comments

Introduced in PostGIS 2.0. This generates html cheat sheets suitable for quick reference or for student handouts. This requires `xsltproc` to build and will generate 4 files in `doc` folder `topology_cheatsheet.html`, `tiger_geocoder_cheatsheet.html`, `raster_cheatsheet.html`, `postgis_cheatsheet.html`

You can download some pre-built ones available in html and pdf from [PostGIS / PostgreSQL Study Guides](#)

make cheatsheets

2.4.3 Building PostGIS Extensions and Deploying them

The PostGIS extensions are built and installed automatically if you are using PostgreSQL 9.1+.

If you are building from source repository, you need to build the function descriptions first. These get built if you have docbook installed. You can also manually build with the statement:

make comments

Building the comments is not necessary if you are building from a release tar ball since these are packaged pre-built with the tar ball already.

If you are building against PostgreSQL 9.1, the extensions should automatically build as part of the `make install` process. You can if needed build from the extensions folders or copy files if you need them on a different server.

```
cd extensions
cd postgis
make clean
make
make install
cd ..
cd postgis_topology
make clean
make
make install
cd ..
cd postgis_sfcgal
make clean
```

```

make
make install

cd ..
cd address_standardizer
make clean
make
make install
make installcheck

cd ..
cd postgis_tiger_geocoder
make clean
make
make install
make installcheck

```

The extension files will always be the same for the same version of PostGIS regardless of OS, so it is fine to copy over the extension files from one OS to another as long as you have the PostGIS binaries already installed on your servers.

If you want to install the extensions manually on a separate server different from your development, You need to copy the following files from the extensions folder into the PostgreSQL / share / extension folder of your PostgreSQL install as well as the needed binaries for regular PostGIS if you don't have them already on the server.

- These are the control files that denote information such as the version of the extension to install if not specified. `postgis.control`, `postgis_topology.control`.
- All the files in the /sql folder of each extension. Note that these need to be copied to the root of the PostgreSQL share/extension folder `extensions/postgis/sql/*.sql`, `extensions/postgis_topology/sql/*.sql`

Once you do that, you should see `postgis`, `postgis_topology` as available extensions in PgAdmin -> extensions.

If you are using psql, you can verify that the extensions are installed by running this query:

```

SELECT name, default_version, installed_version
FROM pg_available_extensions WHERE name LIKE 'postgis%' or name LIKE 'address%';

```

name	default_version	installed_version
address_standardizer	2.3.8	2.3.8
address_standardizer_data_us	2.3.8	2.3.8
postgis	2.3.8	2.3.8
postgis_sfcgal	2.3.8	
postgis_tiger_geocoder	2.3.8	2.3.8
postgis_topology	2.3.8	

(6 rows)

If you have the extension installed in the database you are querying, you'll see mention in the `installed_version` column. If you get no records back, it means you don't have postgis extensions installed on the server at all. PgAdmin III 1.14+ will also provide this information in the `extensions` section of the database browser tree and will even allow upgrade or uninstall by right-clicking.

If you have the extensions available, you can install postgis extension in your database of choice by either using pgAdmin extension interface or running these sql commands:

```

CREATE EXTENSION postgis;
CREATE EXTENSION postgis_sfcgal;
CREATE EXTENSION fuzzystrmatch; --needed for postgis_tiger_geocoder
--optional used by postgis_tiger_geocoder, or can be used standalone
CREATE EXTENSION address_standardizer;
CREATE EXTENSION address_standardizer_data_us;
CREATE EXTENSION postgis_tiger_geocoder;
CREATE EXTENSION postgis_topology;

```

In `psql` you can use to see what versions you have installed and also what schema they are installed.

```
\connect mygisdb
\x
\dx postgis*
```

```
List of installed extensions
-[ RECORD 1 ]-----
Name          | postgis
Version       | 2.3.8
Schema        | public
Description   | PostGIS geometry, geography, and raster spat..
-[ RECORD 2 ]-----
Name          | postgis_tiger_geocoder
Version       | 2.3.8
Schema        | tiger
Description   | PostGIS tiger geocoder and reverse geocoder
-[ RECORD 3 ]-----
Name          | postgis_topology
Version       | 2.3.8
Schema        | topology
Description   | PostGIS topology spatial types and functions
```

Warning

Extension tables `spatial_ref_sys`, `layer`, `topology` can not be explicitly backed up. They can only be backed up when the respective `postgis` or `postgis_topology` extension is backed up, which only seems to happen when you backup the whole database. As of PostGIS 2.0.1, only `srid` records not packaged with PostGIS are backed up when the database is backed up so don't go around changing `srids` we package and expect your changes to be there. Put in a ticket if you find an issue. The structures of extension tables are never backed up since they are created with `CREATE EXTENSION` and assumed to be the same for a given version of an extension. These behaviors are built into the current PostgreSQL extension model, so nothing we can do about it.

If you installed 2.3.8, without using our wonderful extension system, you can change it to be extension based by first upgrading to the latest micro version running the upgrade scripts: `postgis_upgrade_22_minor.sql`, `raster_upgrade_22_minor.sql`, `topology_upgrade_22_minor.sql`.

If you installed `postgis` without raster support, you'll need to install raster support first (using the full `rtpostgis.sql`

Then you can run the below commands to package the functions in their respective extension.

```
CREATE EXTENSION postgis FROM unpackaged;
CREATE EXTENSION postgis_topology FROM unpackaged;
CREATE EXTENSION postgis_tiger_geocoder FROM unpackaged;
```

2.4.4 Testing

If you wish to test the PostGIS build, run

make check

The above command will run through various checks and regression tests using the generated library against an actual PostgreSQL database.

**Note**

If you configured PostGIS using non-standard PostgreSQL, GEOS, or Proj4 locations, you may need to add their library locations to the LD_LIBRARY_PATH environment variable.

**Caution**

Currently, the **make check** relies on the PATH and PGPORT environment variables when performing the checks - it does *not* use the PostgreSQL version that may have been specified using the configuration parameter **--with-pgconfig**. So make sure to modify your PATH to match the detected PostgreSQL installation during configuration or be prepared to deal with the impending headaches.

If successful, the output of the test should be similar to the following:

```
CUnit - A unit testing framework for C - Version 2.1-2
http://cunit.sourceforge.net/

Suite: computational_geometry
  Test: test_lw_segment_side ...passed
  Test: test_lw_segment_intersects ...passed
  Test: test_lwline_crossing_short_lines ...passed
  Test: test_lwline_crossing_long_lines ...passed

The `postgis_tiger_geocoder` and `address_standardizer` extensions, currently only support the standard PostgreSQL `installcheck`. To test these use the below. Note: the `make install` is not necessary if you already did `make install` at root of PostGIS code folder.

For `address_standardizer`:

```

cd extensions/address_standardizer
make install
make installcheck

```

Output should look like:

```

===== dropping database "contrib_regression" =====
DROP DATABASE
===== creating database "contrib_regression" =====

```

```

CREATE DATABASE
ALTER DATABASE
===== running regression test queries =====
test test-init-extensions      ... ok
test test-parseaddress        ... ok
test test-standardize_address_1 ... ok
test test-standardize_address_2 ... ok

=====
All 4 tests passed.
=====

```

For tiger geocoder, make sure you have postgis and fuzzystrmatch extensions available in your PostgreSQL instance. The address_standardizer tests will also kick in if you built postgis with address_standardizer support:

```

cd extensions/postgis_tiger_geocoder
make install
make installcheck

```

output should look like:

```

===== dropping database "contrib_regression" =====
DROP DATABASE
===== creating database "contrib_regression" =====
CREATE DATABASE
ALTER DATABASE
===== installing fuzzystrmatch =====
CREATE EXTENSION
===== installing postgis =====
CREATE EXTENSION
===== installing postgis_tiger_geocoder =====
CREATE EXTENSION
===== installing address_standardizer =====
CREATE EXTENSION
===== running regression test queries =====
test test-normalize_address    ... ok
test test-pagc_normalize_address ... ok

=====
All 2 tests passed.
=====

```

2.4.5 Installation

To install PostGIS, type

make install

This will copy the PostGIS installation files into their appropriate subdirectory specified by the **--prefix** configuration parameter. In particular:

- The loader and dumper binaries are installed in [prefix]/bin.
- The SQL files, such as postgis.sql, are installed in [prefix]/share/contrib.
- The PostGIS libraries are installed in [prefix]/lib.

If you previously ran the **make comments** command to generate the postgis_comments.sql, raster_comments.sql file, install the sql file by running

make comments-install

**Note**

`postgis_comments.sql`, `raster_comments.sql`, `topology_comments.sql` was separated from the typical build and installation targets since with it comes the extra dependency of **xsltproc**.

2.5 Creating a spatial database using EXTENSIONS

If you are using PostgreSQL 9.1+ and have compiled and installed the extensions/ postgis modules, you can create a spatial database the new way.

createdb [yourdatabase]

The core postgis extension installs PostGIS geometry, geography, raster, spatial_ref_sys and all the functions and comments with a simple:

```
CREATE EXTENSION postgis;
```

command.

```
psql -d [yourdatabase] -c "CREATE EXTENSION postgis;"
```

Topology is packaged as a separate extension and installable with command:

```
psql -d [yourdatabase] -c "CREATE EXTENSION postgis_topology;"
```

If you plan to restore an old backup from prior versions in this new db, run:

```
psql -d [yourdatabase] -f legacy.sql
```

You can later run `uninstall_legacy.sql` to get rid of the deprecated functions after you are done with restoring and cleanup.

2.6 Create a spatially-enabled database without using extensions

**Note**

This is generally only needed if you built-PostGIS without raster support. Since raster functions are part of the postgis extension, extension support is not enabled if PostGIS is built without raster.

The first step in creating a PostGIS database is to create a simple PostgreSQL database.

createdb [yourdatabase]

Many of the PostGIS functions are written in the PL/pgSQL procedural language. As such, the next step to create a PostGIS database is to enable the PL/pgSQL language in your new database. This is accomplish by the command below command. For PostgreSQL 8.4+, this is generally already installed

createlang plpgsql [yourdatabase]

Now load the PostGIS object and function definitions into your database by loading the `postgis.sql` definitions file (located in `[prefix]/share/contrib` as specified during the configuration step).

```
psql -d [yourdatabase] -f postgis.sql
```

For a complete set of EPSG coordinate system definition identifiers, you can also load the `spatial_ref_sys.sql` definitions file and populate the `spatial_ref_sys` table. This will permit you to perform `ST_Transform()` operations on geometries.

```
psql -d [yourdatabase] -f spatial_ref_sys.sql
```

If you wish to add comments to the PostGIS functions, the final step is to load the `postgis_comments.sql` into your spatial database. The comments can be viewed by simply typing `\dd [function_name]` from a `psql` terminal window.

```
psql -d [yourdatabase] -f postgis_comments.sql
```

Install raster support

```
psql -d [yourdatabase] -f rtpostgis.sql
```

Install raster support comments. This will provide quick help info for each raster function using `psql` or PgAdmin or any other PostgreSQL tool that can show function comments

```
psql -d [yourdatabase] -f raster_comments.sql
```

Install topology support

```
psql -d [yourdatabase] -f topology/topology.sql
```

Install topology support comments. This will provide quick help info for each topology function / type using `psql` or PgAdmin or any other PostgreSQL tool that can show function comments

```
psql -d [yourdatabase] -f topology/topology_comments.sql
```

If you plan to restore an old backup from prior versions in this new db, run:

```
psql -d [yourdatabase] -f legacy.sql
```

**Note**

There is an alternative `legacy_minimal.sql` you can run instead which will install barebones needed to recover tables and work with apps like MapServer and GeoServer. If you have views that use things like distance / length etc, you'll need the full blown `legacy.sql`

You can later run `uninstall_legacy.sql` to get rid of the deprecated functions after you are done with restoring and cleanup.

2.7 Installing and Using the address standardizer

The `address_standardizer` extension used to be a separate package that required separate download. From PostGIS 2.2 on, it is now bundled in. For more information about the `address_standardize`, what it does, and how to configure it for your needs, refer to Chapter 12.

This standardizer can be used in conjunction with the PostGIS packaged tiger geocoder extension as a replacement for the `Normalize_Address` discussed. To use as replacement refer to Section 2.8.3. You can also use it as a building block for your own geocoder or use it to standardize your addresses for easier compare of addresses.

The address standardizer relies on PCRE which is usually already installed on many Nix systems, but you can download the latest at: <http://www.pcre.org>. If during Section 2.4.1, PCRE is found, then the address standardizer extension will automatically be built. If you have a custom pcre install you want to use instead, pass to configure `--with-pcredir=/path/to/pcre` where `/path/to/pcre` is the root folder for your pcre include and lib directories.

For Windows users, the PostGIS 2.1+ bundle is packaged with the `address_standardizer` already so no need to compile and can move straight to `CREATE EXTENSION` step.

Once you have installed, you can connect to your database and run the SQL:

```
CREATE EXTENSION address_standardizer;
```

The following test requires no rules, gaz, or lex tables

```
SELECT num, street, city, state, zip
FROM parse_address('1 Devonshire Place, Boston, MA 02109');
```

Output should be

```

num |          street          | city | state | zip
-----+-----+-----+-----+-----
1   | Devonshire Place PH301 | Boston | MA    | 02109

```

2.7.1 Installing Regexp::Assemble

Perl Regexp::Assemble is no longer needed for compiling address_standardizer extension since the files it generates are part of the source tree. However if you need to edit the usps-st-city-orig.txt or usps-st-city-orig.txt usps-st-city-ad tx, you need to rebuild parseaddress-stcities.h which does require Regexp::Assemble.

```
cpan Regexp::Assemble
```

or if you are on Ubuntu / Debian you might need to do

```
sudo perl -MCPAN -e "install Regexp::Assemble"
```

2.8 Installing, Upgrading Tiger Geocoder and loading data

Extras like Tiger geocoder may not be packaged in your PostGIS distribution. If you are missing the tiger geocoder extension or want a newer version than what your install comes with, then use the share/extension/postgis_tiger_geocoder.* files from the packages in [Windows Unreleased Versions](#) section for your version of PostgreSQL. Although these packages are for windows, the postgis_tiger_geocoder extension files will work on any OS since the extension is an SQL/plpgsql only extension.

2.8.1 Tiger Geocoder Enabling your PostGIS database: Using Extension

If you are using PostgreSQL 9.1+ and PostGIS 2.1+, you can take advantage of the new extension model for installing tiger geocoder. To do so:

1. First get binaries for PostGIS 2.1+ or compile and install as usual. This should install the necessary extension files as well for tiger geocoder.
2. Connect to your database via psql or pgAdmin or some other tool and run the following SQL commands. Note that if you are installing in a database that already has postgis, you don't need to do the first step. If you have fuzzystmatch extension already installed, you don't need to do the second step either.

```

CREATE EXTENSION postgis;
CREATE EXTENSION fuzzystmatch;
--this one is optional if you want to use the rules based standardizer ( ←
    pagc_normalize_address)
CREATE EXTENSION address_standardizer;
CREATE EXTENSION postgis_tiger_geocoder;

```

If you already have postgis_tiger_geocoder extension installed, and just want to update to the latest run:

```

ALTER EXTENSION postgis UPDATE;
ALTER EXTENSION postgis_tiger_geocoder UPDATE;

```

If you made custom entries or changes to tiger.loader_platform and tiger.loader_variables you may need to update these.

3. To confirm your install is working correctly, run this sql in your database:

```

SELECT na.address, na.streetname,na.streotypeabbrev, na.zip
FROM normalize_address('1 Devonshire Place, Boston, MA 02109') AS na;

```

Which should output

```
address | streetname | streettypeabbrev | zip
-----+-----+-----+-----
      1 | Devonshire | Pl                | 02109
```

4. Create a new record in `tiger.loader_platform` table with the paths of your executables and server.

So for example to create a profile called `debbie` that follows `sh` convention. You would do:

```
INSERT INTO tiger.loader_platform(os, declare_sect, pgbin, wget, unzip_command, psql, ↵
    path_sep,
    loader, environ_set_command, county_process_command)
SELECT 'debbie', declare_sect, pgbin, wget, unzip_command, psql, path_sep,
    loader, environ_set_command, county_process_command
FROM tiger.loader_platform
WHERE os = 'sh';
```

And then edit the paths in the `declare_sect` column to those that fit Debbie's `pg`, `unzip`, `shp2pgsql`, `psql`, etc path locations. If you don't edit this `loader_platform` table, it will just contain common case locations of items and you'll have to edit the generated script after the script is generated.

5. Create a folder called `gisdata` on root of server or your local pc if you have a fast network connection to the server. This folder is where the tiger files will be downloaded to and processed. If you are not happy with having the folder on the root of the server, or simply want to change to a different folder for staging, then edit the field `staging_fold` in the `tiger.loader_variables` table.
6. Create a folder called `temp` in the `gisdata` folder or wherever you designated the `staging_fold` to be. This will be the folder where the loader extracts the downloaded tiger data.
7. Then run the [Loader_Generate_Nation_Script](#) SQL function make sure to use the name of your custom profile and copy the script to a `.sh` or `.bat` file. So for example to build the nation load:

```
psql -c "SELECT Loader_Generate_Nation_Script('debbie')" -d geocoder -tA > /gisdata/ ↵
    nation_script_load.sh
```

8. Run the generated nation load commandline scripts.

```
cd /gisdata
sh nation_script_load.sh
```

9. After you are done running the nation script, you should have three tables in your `tiger_data` schema and they should be filled with data. Confirm you do by doing the following queries from `psql` or `pgAdmin`

```
SELECT count(*) FROM tiger_data.county_all;
```

```
count
-----
   3233
(1 row)
```

```
SELECT count(*) FROM tiger_data.state_all;
```

```
count
-----
    56
(1 row)
```

10. By default the tables corresponding to `bg`, `tract`, `tabblock` are not loaded. These tables are not used by the geocoder but are used by folks for population statistics. If you wish to load them as part of your state loads, run the following statement to enable them.

```
UPDATE tiger.loader_lookuptables SET load = true WHERE load = false AND lookup_name IN (
    'tract', 'bg', 'tabblock');
```

Alternatively you can load just these tables after loading state data using the [Loader_Generate_Census_Script](#)

- For each state you want to load data for, generate a state script [Loader_Generate_Script](#).

Warning

DO NOT Generate the state script until you have already loaded the nation data, because the state script utilizes county list loaded by nation script.

- ```
psql -c "SELECT Loader_Generate_Script(ARRAY['MA'], 'debbie')" -d geocoder -tA > /
gisdata/ma_load.sh
```

- Run the generated commandline scripts.

```
cd /gisdata
sh ma_load.sh
```

- After you are done loading all data or at a stopping point, it's a good idea to analyze all the tiger tables to update the stats (include inherited stats)

```
SELECT install_missing_indexes();
vacuum analyze verbose tiger.addr;
vacuum analyze verbose tiger.edges;
vacuum analyze verbose tiger.faces;
vacuum analyze verbose tiger.featnames;
vacuum analyze verbose tiger.place;
vacuum analyze verbose tiger.cousub;
vacuum analyze verbose tiger.county;
vacuum analyze verbose tiger.state;
vacuum analyze verbose tiger.zip_lookup_base;
vacuum analyze verbose tiger.zip_state;
vacuum analyze verbose tiger.zip_state_loc;
```

### 2.8.1.1 Converting a Tiger Geocoder Regular Install to Extension Model

If you installed the tiger geocoder without using the extension model, you can convert to the extension model as follows:

- Follow instructions in Section [2.8.5](#) for the non-extension model upgrade.
- Connect to your database with psql or pgAdmin and run the following command:

```
CREATE EXTENSION postgis_tiger_geocoder FROM unpackaged;
```

### 2.8.2 Tiger Geocoder Enabling your PostGIS database: Not Using Extensions

First install PostGIS using the prior instructions.

If you don't have an extras folder, download <http://download.osgeo.org/postgis/source/postgis-2.3.8.tar.gz>

```
tar xvfz postgis-2.3.8.tar.gz
```

```
cd postgis-2.3.8/extras/tiger_geocoder
```

Edit the `tiger_loader_2015.sql` (or latest loader file you find, unless you want to load different year) to the paths of your executables server etc or alternatively you can update the `loader_platform` table once installed. If you don't edit this file or the `loader_platform` table, it will just contain common case locations of items and you'll have to edit the generated script after the fact when you run the `Loader_Generate_Nation_Script` and `Loader_Generate_Script` SQL functions.

If you are installing Tiger geocoder for the first time edit either the `create_geocode.bat` script If you are on windows or the `create_geocode.sh` if you are on Linux/Unix/Mac OSX with your PostgreSQL specific settings and run the corresponding script from the commandline.

Verify that you now have a `tiger` schema in your database and that it is part of your database `search_path`. If it is not, add it with a command something along the line of:

```
ALTER DATABASE geocoder SET search_path=public, tiger;
```

The normalizing address functionality works more or less without any data except for tricky addresses. Run this test and verify things look like this:

```
SELECT pprint_addy(normalize_address('202 East Fremont Street, Las Vegas, Nevada 89101')) ←
 As pretty_address;
pretty_address

202 E Fremont St, Las Vegas, NV 89101
```

### 2.8.3 Using Address Standardizer Extension with Tiger geocoder

One of the many complaints of folks is the address normalizer function `Normalize_Address` function that normalizes an address for prepping before geocoding. The normalizer is far from perfect and trying to patch its imperfectness takes a vast amount of resources. As such we have integrated with another project that has a much better address standardizer engine. To use this new `address_standardizer`, you compile the extension as described in Section 2.7 and install as an extension in your database.

Once you install this extension in the same database as you have installed `postgis_tiger_geocoder`, then the `Pgac_Normalize_Ad` can be used instead of `Normalize_Address`. This extension is tiger agnostic, so can be used with other data sources such as international addresses. The tiger geocoder extension does come packaged with its own custom versions of `rules table` (`tiger.pagc_rules`), `gaz table` (`tiger.pagc_gaz`), and `lex table` (`tiger.pagc_lex`). These you can add and update to improve your standardizing experience for your own needs.

### 2.8.4 Loading Tiger Data

The instructions for loading data are available in a more detailed form in the `extras/tiger_geocoder/tiger_2011/README`. This just includes the general steps.

The load process downloads data from the census website for the respective nation files, states requested, extracts the files, and then loads each state into its own separate set of state tables. Each state table inherits from the tables defined in `tiger` schema so that its sufficient to just query those tables to access all the data and drop a set of state tables at any time using the `Drop_State_Tables_Generate_Script` if you need to reload a state or just don't need a state anymore.

In order to be able to load data you'll need the following tools:

- A tool to unzip the zip files from census website.  
For Unix like systems: `unzip` executable which is usually already installed on most Unix like platforms.  
For Windows, 7-zip which is a free compress/uncompress tool you can download from <http://www.7-zip.org/>
- `shp2pgsql` commandline which is installed by default when you install PostGIS.
- `wget` which is a web grabber tool usually installed on most Unix/Linux systems.  
If you are on windows, you can get pre-compiled binaries from <http://gnuwin32.sourceforge.net/packages/wget.htm>

If you are upgrading from tiger\_2010, you'll need to first generate and run [Drop\\_Nation\\_Tables\\_Generate\\_Script](#). Before you load any state data, you need to load the nation wide data which you do with [Loader\\_Generate\\_Nation\\_Script](#). Which will generate a loader script for you. [Loader\\_Generate\\_Nation\\_Script](#) is a one-time step that should be done for upgrading (from 2010) and for new installs.

To load state data refer to [Loader\\_Generate\\_Script](#) to generate a data load script for your platform for the states you desire. Note that you can install these piecemeal. You don't have to load all the states you want all at once. You can load them as you need them.

After the states you desire have been loaded, make sure to run the:

```
SELECT install_missing_indexes();
```

as described in [Install\\_Missing\\_Indexes](#).

To test that things are working as they should, try to run a geocode on an address in your state using [Geocode](#)

## 2.8.5 Upgrading your Tiger Geocoder Install

If you have Tiger Geocoder packaged with 2.0+ already installed, you can upgrade the functions at any time even from an interim tar ball if there are fixes you badly need. This will only work for Tiger geocoder not installed with extensions.

If you don't have an extras folder, download <http://download.osgeo.org/postgis/source/postgis-2.3.8.tar.gz>

```
tar xvfz postgis-2.3.8.tar.gz
```

```
cd postgis-2.3.8/extras/tiger_geocoder/tiger_2011
```

Locate the `upgrade_geocoder.bat` script if you are on windows or the `upgrade_geocoder.sh` if you are on Linux/Unix/Mac OSX. Edit the file to have your postgis database credentials.

If you are upgrading from 2010 or 2011, make sure to unremark out the loader script line so you get the latest script for loading 2012 data.

Then run the corresponding script from the commandline.

Next drop all nation tables and load up the new ones. Generate a drop script with this SQL statement as detailed in [Drop\\_Nation\\_Tables\\_Generate\\_Script](#)

```
SELECT drop_nation_tables_generate_script();
```

Run the generated drop SQL statements.

Generate a nation load script with this SELECT statement as detailed in [Loader\\_Generate\\_Nation\\_Script](#)

### For windows

```
SELECT loader_generate_nation_script('windows');
```

### For unix/linux

```
SELECT loader_generate_nation_script('sh');
```

Refer to Section [2.8.4](#) for instructions on how to run the generate script. This only needs to be done once.

#### Note

You can have a mix of 2010/2011 state tables and can upgrade each state separately. Before you upgrade a state to 2011, you first need to drop the 2010 tables for that state using [Drop\\_State\\_Tables\\_Generate\\_Script](#).

## 2.9 Create a spatially-enabled database from a template

Some packaged distributions of PostGIS (in particular the Win32 installers for PostGIS  $\geq$  1.1.5) load the PostGIS functions into a template database called `template_postgis`. If the `template_postgis` database exists in your PostgreSQL installation then it is possible for users and/or applications to create spatially-enabled databases using a single command. Note that in both cases, the database user must have been granted the privilege to create new databases.

From the shell:

```
createdb -T template_postgis my_spatial_db
```

From SQL:

```
postgres=# CREATE DATABASE my_spatial_db TEMPLATE=template_postgis
```

## 2.10 Upgrading

Upgrading existing spatial databases can be tricky as it requires replacement or introduction of new PostGIS object definitions. Unfortunately not all definitions can be easily replaced in a live database, so sometimes your best bet is a dump/reload process. PostGIS provides a SOFT UPGRADE procedure for minor or bugfix releases, and a HARD UPGRADE procedure for major releases.

Before attempting to upgrade PostGIS, it is always worth to backup your data. If you use the `-Fc` flag to `pg_dump` you will always be able to restore the dump with a HARD UPGRADE.

### 2.10.1 Soft upgrade

If you installed your database using extensions, you'll need to upgrade using the extension model as well. If you installed using the old sql script way, then you should upgrade using the sql script way. Please refer to the appropriate.

#### 2.10.1.1 Soft Upgrade Pre 9.1+ or without extensions

This section applies only to those who installed PostGIS not using extensions. If you have extensions and try to upgrade with this approach you'll get messages like:

```
can't drop ... because postgis extension depends on it
```

After compiling and installing (make install) you should find a `postgis_upgrade.sql` and `rtpostgis_upgrade.sql` in the installation folders. For example `/usr/share/postgresql/9.3/contrib/postgis_upgrade.sql`. Install the `postgis_upgrade.sql`. If you have raster functionality installed, you will also need to install the `/usr/share/postgresql/9.3/contrib/postgis_upgrade.sql`. If you are moving from PostGIS 1.\* to PostGIS 2.\* or from PostGIS 2.\* prior to r7409, you need to do a HARD UPGRADE.

```
psql -f postgis_upgrade.sql -d your_spatial_database
```

The same procedure applies to raster and topology extensions, with upgrade files named `rtpostgis_upgrade*.sql` and `topology_upgrade*.sql` respectively. If you need them:

```
psql -f rtpostgis_upgrade.sql -d your_spatial_database
```

```
psql -f topology_upgrade.sql -d your_spatial_database
```

**Note**

If you can't find the `postgis_upgrade*.sql` specific for upgrading your version you are using a version too early for a soft upgrade and need to do a **HARD UPGRADE**.

The `PostGIS_Full_Version` function should inform you about the need to run this kind of upgrade using a "procs need upgrade" message.

### 2.10.1.2 Soft Upgrade 9.1+ using extensions

If you originally installed PostGIS with extensions, then you need to upgrade using extensions as well. Doing a minor upgrade with extensions, is fairly painless.

```
ALTER EXTENSION postgis UPDATE TO "2.3.8";
ALTER EXTENSION postgis_topology UPDATE TO "2.3.8";
```

If you get an error notice something like:

```
No migration path defined for ... to 2.3.8
```

Then you'll need to backup your database, create a fresh one as described in Section 2.5 and then restore your backup ontop of this new database.

If you get a notice message like:

```
Version "2.3.8" of extension "postgis" is already installed
```

Then everything is already up to date and you can safely ignore it. **UNLESS** you're attempting to upgrade from an SVN version to the next (which doesn't get a new version number); in that case you can append "next" to the version string, and next time you'll need to drop the "next" suffix again:

```
ALTER EXTENSION postgis UPDATE TO "2.3.8next";
ALTER EXTENSION postgis_topology UPDATE TO "2.3.8next";
```

**Note**

If you installed PostGIS originally without a version specified, you can often skip the reinstallation of postgis extension before restoring since the backup just has `CREATE EXTENSION postgis` and thus picks up the newest latest version during restore.

## 2.10.2 Hard upgrade

By **HARD UPGRADE** we mean full dump/reload of postgis-enabled databases. You need a **HARD UPGRADE** when PostGIS objects' internal storage changes or when **SOFT UPGRADE** is not possible. The **Release Notes** appendix reports for each version whether you need a dump/reload (**HARD UPGRADE**) to upgrade.

The dump/reload process is assisted by the `postgis_restore.pl` script which takes care of skipping from the dump all definitions which belong to PostGIS (including old ones), allowing you to restore your schemas and data into a database with PostGIS installed without getting duplicate symbol errors or bringing forward deprecated objects.

Supplementary instructions for windows users are available at [Windows Hard upgrade](#).

The Procedure is as follows:

1. Create a "custom-format" dump of the database you want to upgrade (let's call it `olddb`) include binary blobs (-b) and verbose (-v) output. The user can be the owner of the db, need not be postgres super account.

```
pg_dump -h localhost -p 5432 -U postgres -Fc -b -v -f "/somepath/olddb.backup" olddb
```

2. Do a fresh install of PostGIS in a new database -- we'll refer to this database as `newdb`. Please refer to Section 2.6 and Section 2.5 for instructions on how to do this.

The `spatial_ref_sys` entries found in your dump will be restored, but they will not override existing ones in `spatial_ref_sys`. This is to ensure that fixes in the official set will be properly propagated to restored databases. If for any reason you really want your own overrides of standard entries just don't load the `spatial_ref_sys.sql` file when creating the new db.

If your database is really old or you know you've been using long deprecated functions in your views and functions, you might need to load `legacy.sql` for all your functions and views etc. to properly come back. Only do this if `_really_` needed. Consider upgrading your views and functions before dumping instead, if possible. The deprecated functions can be later removed by loading `uninstall_legacy.sql`.

3. Restore your backup into your fresh `newdb` database using `postgis_restore.pl`. Unexpected errors, if any, will be printed to the standard error stream by `psql`. Keep a log of those.

```
perl utils/postgis_restore.pl "/somepath/olddb.backup" | psql -h localhost -p 5432 -U postgres newdb 2> errors.txt
```

Errors may arise in the following cases:

1. Some of your views or functions make use of deprecated PostGIS objects. In order to fix this you may try loading `legacy.sql` script prior to restore or you'll have to restore to a version of PostGIS which still contains those objects and try a migration again after porting your code. If the `legacy.sql` way works for you, don't forget to fix your code to stop using deprecated functions and drop them loading `uninstall_legacy.sql`.
2. Some custom records of `spatial_ref_sys` in dump file have an invalid SRID value. Valid SRID values are bigger than 0 and smaller than 999000. Values in the 999000..999999 range are reserved for internal use while values > 999999 can't be used at all. All your custom records with invalid SRIDs will be retained, with those > 999999 moved into the reserved range, but the `spatial_ref_sys` table would lose a check constraint guarding for that invariant to hold and possibly also its primary key ( when multiple invalid SRIDS get converted to the same reserved SRID value ).

In order to fix this you should copy your custom SRS to a SRID with a valid value (maybe in the 910000..910999 range), convert all your tables to the new srid (see [UpdateGeometrySRID](#)), delete the invalid entry from `spatial_ref_sys` and reconstruct the check(s) with:

```
ALTER TABLE spatial_ref_sys ADD CONSTRAINT spatial_ref_sys_srid_check check (srid > 0 AND srid < 999000);
```

```
ALTER TABLE spatial_ref_sys ADD PRIMARY KEY(srid);
```

## 2.11 Common Problems during installation

There are several things to check when your installation or upgrade doesn't go as you expected.

1. Check that you have installed PostgreSQL 9.2 or newer, and that you are compiling against the same version of the PostgreSQL source as the version of PostgreSQL that is running. Mix-ups can occur when your (Linux) distribution has already installed PostgreSQL, or you have otherwise installed PostgreSQL before and forgotten about it. PostGIS will only work with PostgreSQL 9.2 or newer, and strange, unexpected error messages will result if you use an older version. To check the version of PostgreSQL which is running, connect to the database using `psql` and run this query:

```
SELECT version();
```

If you are running an RPM based distribution, you can check for the existence of pre-installed packages using the `rpm` command as follows: `rpm -qa | grep postgresql`

2. If your upgrade fails, make sure you are restoring into a database that already has PostGIS installed.

```
SELECT postgis_full_version();
```

Also check that configure has correctly detected the location and version of PostgreSQL, the Proj4 library and the GEOS library.

1. The output from configure is used to generate the `postgis_config.h` file. Check that the `POSTGIS_PGSQL_VERSION`, `POSTGIS_PROJ_VERSION` and `POSTGIS_GEOS_VERSION` variables have been set correctly.

## 2.12 Loader/Dumper

The data loader and dumper are built and installed automatically as part of the PostGIS build. To build and install them manually:

```
cd postgis-2.3.8/loader
make
make install
```

The loader is called `shp2pgsql` and converts ESRI Shape files into SQL suitable for loading in PostGIS/PostgreSQL. The dumper is called `pgsql2shp` and converts PostGIS tables (or queries) into ESRI Shape files. For more verbose documentation, see the online help, and the manual pages.

## Chapter 3

# PostGIS Frequently Asked Questions

1. *Where can I find tutorials, guides and workshops on working with PostGIS*

OpenGeo has a step by step tutorial guide workshop [Introduction to PostGIS](#). It includes packaged data as well as intro to working with OpenGeo Suite. It is probably the best tutorial on PostGIS. BostonGIS also has a [PostGIS almost idiot's guide on getting started](#). That one is more focused on the windows user.

2. *My applications and desktop tools worked with PostGIS 1.5, but they don't work with PostGIS 2.0. How do I fix this?*

A lot of deprecated functions were removed from the PostGIS code base in PostGIS 2.0. This has affected applications in addition to third-party tools such as Geoserver, MapServer, QuantumGIS, and OpenJump to name a few. There are a couple of ways to resolve this. For the third-party apps, you can try to upgrade to the latest versions of these which have many of these issues fixed. For your own code, you can change your code to not use the functions removed. Most of these functions are non ST\_ aliases of ST\_Union, ST\_Length etc. and as a last resort, install the whole of `legacy.sql` or just the portions of `legacy.sql` you need. The `legacy.sql` file is located in the same folder as `postgis.sql`. You can install this file after you have installed `postgis.sql` and `spatial_ref_sys.sql` to get back all the 200 some-odd old functions we removed.

3. *When I load OpenStreetMap data with `osm2pgsql`, I'm getting an error failed: ERROR: operator class "gist\_geometry\_ops" does not exist for access method "gist" Error occurred. This worked fine in PostGIS 1.5.*

In PostGIS 2, the default geometry operator class `gist_geometry_ops` was changed to `gist_geometry_ops_2d` and the `gist_geometry_ops` was completely removed. This was done because PostGIS 2 also introduced Nd spatial indexes for 3D support and the old name was deemed confusing and a misnomer. Some older applications that as part of the process create tables and indexes, explicitly referenced the operator class name. This was unnecessary if you want the default 2D index. So if you manage said good, change index creation from: BAD:

```
CREATE INDEX idx_my_table_geom ON my_table USING gist (geom gist_geometry_ops);
```

To GOOD:

```
CREATE INDEX idx_my_table_geom ON my_table USING gist (geom);
```

The only case where you WILL need to specify the operator class is if you want a 3D spatial index as follows:

```
CREATE INDEX idx_my_super3d_geom ON my_super3d USING gist (geom gist_geometry_ops_nd);
```

If you are unfortunate to be stuck with compiled code you can't change that has the old `gist_geometry_ops` hard-coded, then you can create the old class using the `legacy_gist.sql` packaged in PostGIS 2.0.2+. However if you use this fix, you are advised to at a later point drop the index and recreate it without the operator class. This will save you grief in the future when you need to upgrade again.

4. *I'm running PostgreSQL 9.0 and I can no longer read/view geometries in OpenJump, Safe FME, and some other tools?*

In PostgreSQL 9.0+, the default encoding for bytea data has been changed to hex and older JDBC drivers still assume escape format. This has affected some applications such as Java applications using older JDBC drivers or .NET applications that use the older `npgsql` driver that expect the old behavior of `ST_AsBinary`. There are two approaches to

getting this to work again. You can upgrade your JDBC driver to the latest PostgreSQL 9.0 version which you can get from <http://jdbc.postgresql.org/download.html>. If you are running a .NET app, you can use Npgsql 2.0.11 or higher which you can download from [http://pgfoundry.org/frs/?group\\_id=1000140](http://pgfoundry.org/frs/?group_id=1000140) and as described on [Francisco Figueiredo's Npgsql 2.0.11 released blog entry](#). If upgrading your PostgreSQL driver is not an option, then you can set the default back to the old behavior with the following change:

```
ALTER DATABASE mypostgisdb SET bytea_output='escape';
```

5. *I tried to use PgAdmin to view my geometry column and it is blank, what gives?*

PgAdmin doesn't show anything for large geometries. The best ways to verify you do have data in your geometry columns are?

```
-- this should return no records if all your geom fields are filled in
SELECT somefield FROM mytable WHERE geom IS NULL;
```

```
-- To tell just how large your geometry is do a query of the form
--which will tell you the most number of points you have in any of your geometry ↵
columns
SELECT MAX(ST_NPoints(geom)) FROM sometable;
```

6. *What kind of geometric objects can I store?*

You can store Point, LineString, Polygon, MultiPoint, MultiLineString, MultiPolygon, and GeometryCollection geometries. In PostGIS 2.0 and above you can also store TINs and Polyhedral Surfaces in the basic geometry type. These are specified in the Open GIS Well Known Text Format (with Z, M, and ZM extensions). There are three data types currently supported. The standard OGC geometry data type which uses a planar coordinate system for measurement, the geography data type which uses a geodetic coordinate system, with calculations on either a sphere or spheroid. The newest family member of the PostGIS spatial type family is raster for storing and analyzing raster data. Raster has its very own FAQ. Refer to Chapter 10 and Chapter 9 for more details.

7. *I'm all confused. Which data store should I use geometry or geography?*

Short Answer: geography is a newer data type that supports long range distances measurements, but most computations on it are slower than they are on geometry. If you use geography, you don't need to learn much about planar coordinate systems. Geography is generally best if all you care about is measuring distances and lengths and you have data from all over the world. Geometry data type is an older data type that has many more functions supporting it, enjoys greater support from third party tools, and operations on it are generally faster -- sometimes as much as 10 fold faster for larger geometries. Geometry is best if you are pretty comfortable with spatial reference systems or you are dealing with localized data where all your data fits in a single [spatial reference system \(SRID\)](#), or you need to do a lot of spatial processing. Note: It is fairly easy to do one-off conversions between the two types to gain the benefits of each. Refer to Section 14.11 to see what is currently supported and what is not. Long Answer: Refer to our more lengthy discussion in the Section 4.2.2 and [function type matrix](#).

8. *I have more intense questions about geography, such as how big of a geographic region can I stuff in a geography column and still get reasonable answers. Are there limitations such as poles, everything in the field must fit in a hemisphere (like SQL Server 2008 has), speed etc?*

Your questions are too deep and complex to be adequately answered in this section. Please refer to our Section 4.2.3.

9. *How do I insert a GIS object into the database?*

First, you need to create a table with a column of type "geometry" or "geography" to hold your GIS data. Storing geography type data is a little different than storing geometry. Refer to Section 4.2.1 for details on storing geography. For geometry: Connect to your database with psql and try the following SQL:

```
CREATE TABLE gtest (gid serial primary key, name varchar(20)
, geom geometry(LINESTRING));
```

If the geometry column definition fails, you probably have not loaded the PostGIS functions and objects into this database or are using a pre-2.0 version of PostGIS. See the Section 2.4. Then, you can insert a geometry into the table using a SQL insert statement. The GIS object itself is formatted using the OpenGIS Consortium "well-known text" format:

```
INSERT INTO gtest (ID, NAME, GEOM)
VALUES (
 1,
 'First Geometry',
 ST_GeomFromText('LINESTRING(2 3,4 5,6 5,7 8)')
);
```

For more information about other GIS objects, see the [object reference](#). To view your GIS data in the table:

```
SELECT id, name, ST_AsText(geom) AS geom FROM gtest;
```

The return value should look something like this:

```
id | name | geom
---+-----+-----
 1 | First Geometry | LINESTRING(2 3,4 5,6 5,7 8)
(1 row)
```

#### 10. How do I construct a spatial query?

The same way you construct any other database query, as an SQL combination of return values, functions, and boolean tests. For spatial queries, there are two issues that are important to keep in mind while constructing your query: is there a spatial index you can make use of; and, are you doing expensive calculations on a large number of geometries. In general, you will want to use the "intersects operator" (&&) which tests whether the bounding boxes of features intersect. The reason the && operator is useful is because if a spatial index is available to speed up the test, the && operator will make use of this. This can make queries much much faster. You will also make use of spatial functions, such as Distance(), ST\_Intersects(), ST\_Contains() and ST\_Within(), among others, to narrow down the results of your search. Most spatial queries include both an indexed test and a spatial function test. The index test serves to limit the number of return tuples to only tuples that *might* meet the condition of interest. The spatial functions are then use to test the condition exactly.

```
SELECT id, the_geom
FROM thetable
WHERE
 ST_Contains(the_geom, 'POLYGON((0 0, 0 10, 10 10, 10 0, 0 0))');
```

#### 11. How do I speed up spatial queries on large tables?

Fast queries on large tables is the *raison d'être* of spatial databases (along with transaction support) so having a good index is important. To build a spatial index on a table with a `geometry` column, use the "CREATE INDEX" function as follows:

```
CREATE INDEX [indexname] ON [tablename] USING GIST ([geometrycolumn]);
```

The "USING GIST" option tells the server to use a GiST (Generalized Search Tree) index.

#### Note

GiST indexes are assumed to be lossy. Lossy indexes uses a proxy object (in the spatial case, a bounding box) for building the index.

You should also ensure that the PostgreSQL query planner has enough information about your index to make rational decisions about when to use it. To do this, you have to "gather statistics" on your geometry tables. For PostgreSQL 8.0.x and greater, just run the `VACUUM ANALYZE` command. For PostgreSQL 7.4.x and below, run the `SELECT UPDATE_GEOMETRY_STATS()` command.

#### 12. Why aren't PostgreSQL R-Tree indexes supported?

Early versions of PostGIS used the PostgreSQL R-Tree indexes. However, PostgreSQL R-Trees have been completely discarded since version 0.6, and spatial indexing is provided with an R-Tree-over-GiST scheme. Our tests have shown search speed for native R-Tree and GiST to be comparable. Native PostgreSQL R-Trees have two limitations which make them undesirable for use with GIS features (note that these limitations are due to the current PostgreSQL native R-Tree implementation, not the R-Tree concept in general):

- R-Tree indexes in PostgreSQL cannot handle features which are larger than 8K in size. GiST indexes can, using the "lossy" trick of substituting the bounding box for the feature itself.
- R-Tree indexes in PostgreSQL are not "null safe", so building an index on a geometry column which contains null geometries will fail.

13. *Why should I use the `AddGeometryColumn()` function and all the other OpenGIS stuff?*

If you do not want to use the OpenGIS support functions, you do not have to. Simply create tables as in older versions, defining your geometry columns in the CREATE statement. All your geometries will have SRIDs of -1, and the OpenGIS meta-data tables will *not* be filled in properly. However, this will cause most applications based on PostGIS to fail, and it is generally suggested that you do use `AddGeometryColumn()` to create geometry tables. MapServer is one application which makes use of the `geometry_columns` meta-data. Specifically, MapServer can use the SRID of the geometry column to do on-the-fly reprojection of features into the correct map projection.

14. *What is the best way to find all objects within a radius of another object?*

To use the database most efficiently, it is best to do radius queries which combine the radius test with a bounding box test: the bounding box test uses the spatial index, giving fast access to a subset of data which the radius test is then applied to. The `ST_DWithin(geometry, geometry, distance)` function is a handy way of performing an indexed distance search. It works by creating a search rectangle large enough to enclose the distance radius, then performing an exact distance search on the indexed subset of results. For example, to find all objects with 100 meters of `POINT(1000 1000)` the following query would work well:

```
SELECT * FROM geotable
WHERE ST_DWithin(geocolumn, 'POINT(1000 1000)', 100.0);
```

15. *How do I perform a coordinate reprojection as part of a query?*

To perform a reprojection, both the source and destination coordinate systems must be defined in the `SPATIAL_REF_SYS` table, and the geometries being reprojected must already have an SRID set on them. Once that is done, a reprojection is as simple as referring to the desired destination SRID. The below projects a geometry to NAD 83 long lat. The below will only work if the srid of the `_geom` is not -1 (not undefined spatial ref)

```
SELECT ST_Transform(the_geom, 4269) FROM geotable;
```

16. *I did an `ST_AsEWKT` and `ST_AsText` on my rather large geometry and it returned blank field. What gives?*

You are probably using PgAdmin or some other tool that doesn't output large text. If your geometry is big enough, it will appear blank in these tools. Use PSQL if you really need to see it or output it in WKT.

```
--To check number of geometries are really blank
SELECT count(gid) FROM geotable WHERE the_geom IS NULL;
```

17. *When I do an `ST_Intersects`, it says my two geometries don't intersect when I KNOW THEY DO. What gives?*

This generally happens in two common cases. Your geometry is invalid -- check `ST_IsValid` or you are assuming they intersect because `ST_AsText` truncates the numbers and you have lots of decimals after it is not showing you.

18. *I am releasing software that uses PostGIS, does that mean my software has to be licensed using the GPL like PostGIS? Will I have to publish all my code if I use PostGIS?*

Almost certainly not. As an example, consider Oracle database running on Linux. Linux is GPL, Oracle is not, does Oracle running on Linux have to be distributed using the GPL? No. So your software can use a PostgreSQL/PostGIS database as much as it wants and be under any license you like. The only exception would be if you made changes to the PostGIS source code, and distributed your changed version of PostGIS. In that case you would have to share the code of your changed PostGIS (but not the code of applications running on top of it). Even in this limited case, you would still only have to distribute source code to people you distributed binaries to. The GPL does not require that you *publish* your source code, only that you share it with people you give binaries to.

## Chapter 4

# Using PostGIS: Data Management and Queries

### 4.1 GIS Objects

The GIS objects supported by PostGIS are a superset of the "Simple Features" defined by the OpenGIS Consortium (OGC). As of version 0.9, PostGIS supports all the objects and functions specified in the OGC "Simple Features for SQL" specification.

PostGIS extends the standard with support for 3DZ,3DM and 4D coordinates.

#### 4.1.1 OpenGIS WKB and WKT

The OpenGIS specification defines two standard ways of expressing spatial objects: the Well-Known Text (WKT) form and the Well-Known Binary (WKB) form. Both WKT and WKB include information about the type of the object and the coordinates which form the object.

Examples of the text representations (WKT) of the spatial objects of the features are as follows:

- POINT(0 0)
- LINESTRING(0 0,1 1,1 2)
- POLYGON(((0 0,4 0,4 0,4,0 0),(1 1, 2 1, 2 2, 1 2,1 1)))
- MULTIPOINT((0 0),(1 2))
- MULTILINESTRING((0 0,1 1,1 2),(2 3,3 2,5 4))
- MULTIPOLYGON((((0 0,4 0,4 0,4,0 0),(1 1,2 1,2 2,1 2,1 1)), ((-1 -1,-1 -2,-2 -2,-2 -1,-1 -1)))
- GEOMETRYCOLLECTION(POINT(2 3),LINESTRING(2 3,3 4))

The OpenGIS specification also requires that the internal storage format of spatial objects include a spatial referencing system identifier (SRID). The SRID is required when creating spatial objects for insertion into the database.

Input/Output of these formats are available using the following interfaces:

```
bytea WKB = ST_AsBinary(geometry);
text WKT = ST_AsText(geometry);
geometry = ST_GeomFromWKB(bytea WKB, SRID);
geometry = ST_GeometryFromText(text WKT, SRID);
```

For example, a valid insert statement to create and insert an OGC spatial object would be:

```
INSERT INTO geotable (the_geom, the_name)
VALUES (ST_GeomFromText('POINT(-126.4 45.32)', 312), 'A Place');
```

### 4.1.3 SQL-MM Part 3

The SQL Multimedia Applications Spatial specification extends the simple features for SQL spec by defining a number of circularly interpolated curves.

The SQL-MM definitions include 3dm, 3dz and 4d coordinates, but do not allow the embedding of SRID information.

The well-known text extensions are not yet fully supported. Examples of some simple curved geometries are shown below:

- `CIRCULARSTRING(0 0, 1 1, 1 0)`

`CIRCULARSTRING(0 0, 4 0, 4 4, 0 4, 0 0)`

The `CIRCULARSTRING` is the basic curve type, similar to a `LINestring` in the linear world. A single segment required three points, the start and end points (first and third) and any other point on the arc. The exception to this is for a closed circle, where the start and end points are the same. In this case the second point **MUST** be the center of the arc, ie the opposite side of the circle. To chain arcs together, the last point of the previous arc becomes the first point of the next arc, just like in `LINestring`. This means that a valid circular string must have an odd number of points greater than 1.

- `COMPOUNDCURVE(CIRCULARSTRING(0 0, 1 1, 1 0),(1 0, 0 1))`

A compound curve is a single, continuous curve that has both curved (circular) segments and linear segments. That means that in addition to having well-formed components, the end point of every component (except the last) must be coincident with the start point of the following component.

- `CURVEPOLYGON(CIRCULARSTRING(0 0, 4 0, 4 4, 0 4, 0 0),(1 1, 3 3, 3 1, 1 1))`

Example compound curve in a curve polygon: `CURVEPOLYGON(COMPOUNDCURVE(CIRCULARSTRING(0 0, 2 0, 2 1, 2 3, 4 3),(4 3, 4 5, 1 4, 0 0)), CIRCULARSTRING(1.7 1, 1.4 0.4, 1.6 0.4, 1.6 0.5, 1.7 1))`

A `CURVEPOLYGON` is just like a polygon, with an outer ring and zero or more inner rings. The difference is that a ring can take the form of a circular string, linear string or compound string.

As of PostGIS 1.4 PostGIS supports compound curves in a curve polygon.

- `MULTICURVE((0 0, 5 5),CIRCULARSTRING(4 0, 4 4, 8 4))`

The `MULTICURVE` is a collection of curves, which can include linear strings, circular strings or compound strings.

- `MULTISURFACE(CURVEPOLYGON(CIRCULARSTRING(0 0, 4 0, 4 4, 0 4, 0 0),(1 1, 3 3, 3 1, 1 1)),((10 10, 14 12, 11 10, 10 10),(11 11, 11.5 11, 11 11.5, 11 11)))`

This is a collection of surfaces, which can be (linear) polygons or curve polygons.

#### Note

PostGIS prior to 1.4 does not support compound curves in a curve polygon, but PostGIS 1.4 and above do support the use of Compound Curves in a Curve Polygon.

---

#### Note

All floating point comparisons within the SQL-MM implementation are performed to a specified tolerance, currently 1E-8.

---

## 4.2 PostGIS Geography Type

The geography type provides native support for spatial features represented on "geographic" coordinates (sometimes called "geodetic" coordinates, or "lat/lon", or "lon/lat"). Geographic coordinates are spherical coordinates expressed in angular units (degrees).

---

The basis for the PostGIS geometry type is a plane. The shortest path between two points on the plane is a straight line. That means calculations on geometries (areas, distances, lengths, intersections, etc) can be calculated using cartesian mathematics and straight line vectors.

The basis for the PostGIS geographic type is a sphere. The shortest path between two points on the sphere is a great circle arc. That means that calculations on geographies (areas, distances, lengths, intersections, etc) must be calculated on the sphere, using more complicated mathematics. For more accurate measurements, the calculations must take the actual spheroidal shape of the world into account, and the mathematics becomes very complicated indeed.

Because the underlying mathematics is much more complicated, there are fewer functions defined for the geography type than for the geometry type. Over time, as new algorithms are added, the capabilities of the geography type will expand.

One restriction is that it only supports WGS 84 long lat (SRID:4326). It uses a new data type called geography. None of the GEOS functions support this new type. As a workaround one can convert back and forth between geometry and geography types.

The new geography type uses the PostgreSQL 8.3+ typmod definition format so that a table with a geography field can be added in a single step. All the standard OGC formats except for curves are supported.

### 4.2.1 Geography Basics

The geography type only supports the simplest of simple features. Standard geometry type data will autocast to geography if it is of SRID 4326. You can also use the EWKT and EWKB conventions to insert data.

- POINT: Creating a table with 2d point geometry:

```
CREATE TABLE testgeog(gid serial PRIMARY KEY, the_geog geography(POINT,4326));
```

Creating a table with z coordinate point

```
CREATE TABLE testgeog(gid serial PRIMARY KEY, the_geog geography(POINTZ,4326));
```

- LINESTRING
- POLYGON
- MULTIPOINT
- MULTILINESTRING
- MULTIPOLYGON
- GEOMETRYCOLLECTION

The new geography fields don't get registered in the `geometry_columns`. They get registered in a new view called `geography_columns` which is a view against the system catalogs so is always automatically kept up to date without need for an `AddGeom...` like function.

Now, check the "geography\_columns" view and see that your table is listed.

You can create a new table with a GEOGRAPHY column using the CREATE TABLE syntax. Unlike GEOMETRY, there is no need to run a separate `AddGeometryColumns()` process to register the column in metadata.

```
CREATE TABLE global_points (
 id SERIAL PRIMARY KEY,
 name VARCHAR(64),
 location GEOGRAPHY(POINT,4326)
);
```

Note that the location column has type GEOGRAPHY and that geography type supports two optional modifier: a type modifier that restricts the kind of shapes and dimensions allowed in the column; an SRID modifier that restricts the coordinate reference identifier to a particular number.

Allowable values for the type modifier are: POINT, LINESTRING, POLYGON, MULTIPOINT, MULTILINESTRING, MULTIPOLYGON. The modifier also supports dimensionality restrictions through suffixes: Z, M and ZM. So, for example a modifier of 'LINESTRINGM' would only allow line strings with three dimensions in, and would treat the third dimension as a measure. Similarly, 'POINTZM' would expect four dimensional data.

The SRID modifier is currently of limited use: only 4326 (WGS84) is allowed as a value. If you do not specify an SRID, the a value 0 (undefined spheroid) will be used, and all calculations will proceed using WGS84 anyways.

In the future, alternate SRIDs will allow calculations on spheroids other than WGS84.

Once you have created your table, you can see it in the GEOGRAPHY\_COLUMNS table:

```
-- See the contents of the metadata view
SELECT * FROM geography_columns;
```

You can insert data into the table the same as you would if it was using a GEOMETRY column:

```
-- Add some data into the test table
INSERT INTO global_points (name, location) VALUES ('Town', ST_GeographyFromText('SRID=4326; ↵
POINT(-110 30)'));
INSERT INTO global_points (name, location) VALUES ('Forest', ST_GeographyFromText('SRID ↵
=4326;POINT(-109 29)'));
INSERT INTO global_points (name, location) VALUES ('London', ST_GeographyFromText('SRID ↵
=4326;POINT(0 49)'));
```

Creating an index works the same as GEOMETRY. PostGIS will note that the column type is GEOGRAPHY and create an appropriate sphere-based index instead of the usual planar index used for GEOMETRY.

```
-- Index the test table with a spherical index
CREATE INDEX global_points_gix ON global_points USING GIST (location);
```

Query and measurement functions use units of meters. So distance parameters should be expressed in meters, and return values should be expected in meters (or square meters for areas).

```
-- Show a distance query and note, London is outside the 1000km tolerance
SELECT name FROM global_points WHERE ST_DWithin(location, ST_GeographyFromText('SRID ↵
=4326;POINT(-110 29)'), 1000000);
```

You can see the power of GEOGRAPHY in action by calculating the how close a plane flying from Seattle to London (LINESTRING(-122.33 47.606, 0.0 51.5)) comes to Reykjavik (POINT(-21.96 64.15)).

```
-- Distance calculation using GEOGRAPHY (122.2km)
SELECT ST_Distance('LINESTRING(-122.33 47.606, 0.0 51.5)::geography, 'POINT(-21.96 ↵
64.15):: geography');

-- Distance calculation using GEOMETRY (13.3 "degrees")
SELECT ST_Distance('LINESTRING(-122.33 47.606, 0.0 51.5)::geometry, 'POINT(-21.96 64.15) ↵
':: geometry);
```

The GEOGRAPHY type calculates the true shortest distance over the sphere between Reykjavik and the great circle flight path between Seattle and London.

**Great Circle mapper** The GEOMETRY type calculates a meaningless cartesian distance between Reykjavik and the straight line path from Seattle to London plotted on a flat map of the world. The nominal units of the result might be called "degrees", but the result doesn't correspond to any true angular difference between the points, so even calling them "degrees" is inaccurate.

## 4.2.2 When to use Geography Data type over Geometry data type

The new GEOGRAPHY type allows you to store data in longitude/latitude coordinates, but at a cost: there are fewer functions defined on GEOGRAPHY than there are on GEOMETRY; those functions that are defined take more CPU time to execute.

The type you choose should be conditioned on the expected working area of the application you are building. Will your data span the globe or a large continental area, or is it local to a state, county or municipality?

- If your data is contained in a small area, you might find that choosing an appropriate projection and using `GEOMETRY` is the best solution, in terms of performance and functionality available.
- If your data is global or covers a continental region, you may find that `GEOGRAPHY` allows you to build a system without having to worry about projection details. You store your data in longitude/latitude, and use the functions that have been defined on `GEOGRAPHY`.
- If you don't understand projections, and you don't want to learn about them, and you're prepared to accept the limitations in functionality available in `GEOGRAPHY`, then it might be easier for you to use `GEOGRAPHY` than `GEOMETRY`. Simply load your data up as longitude/latitude and go from there.

Refer to Section [14.11](#) for compare between what is supported for Geography vs. Geometry. For a brief listing and description of Geography functions, refer to Section [14.4](#)

### 4.2.3 Geography Advanced FAQ

1. *Do you calculate on the sphere or the spheroid?*

By default, all distance and area calculations are done on the spheroid. You should find that the results of calculations in local areas match up well with local planar results in good local projections. Over larger areas, the spheroidal calculations will be more accurate than any calculation done on a projected plane. All the geography functions have the option of using a sphere calculation, by setting a final boolean parameter to 'FALSE'. This will somewhat speed up calculations, particularly for cases where the geometries are very simple.

2. *What about the date-line and the poles?*

All the calculations have no conception of date-line or poles, the coordinates are spherical (longitude/latitude) so a shape that crosses the dateline is, from a calculation point of view, no different from any other shape.

3. *What is the longest arc you can process?*

We use great circle arcs as the "interpolation line" between two points. That means any two points are actually joined up two ways, depending on which direction you travel along the great circle. All our code assumes that the points are joined by the \*shorter\* of the two paths along the great circle. As a consequence, shapes that have arcs of more than 180 degrees will not be correctly modelled.

4. *Why is it so slow to calculate the area of Europe / Russia / insert big geographic region here ?*

Because the polygon is so darned huge! Big areas are bad for two reasons: their bounds are huge, so the index tends to pull the feature no matter what query you run; the number of vertices is huge, and tests (distance, containment) have to traverse the vertex list at least once and sometimes N times (with N being the number of vertices in the other candidate feature). As with `GEOMETRY`, we recommend that when you have very large polygons, but are doing queries in small areas, you "denormalize" your geometric data into smaller chunks so that the index can effectively subquery parts of the object and so queries don't have to pull out the whole object every time. Just because you \*can\* store all of Europe in one polygon doesn't mean you \*should\*.

## 4.3 Using OpenGIS Standards

The OpenGIS "Simple Features Specification for SQL" defines standard GIS object types, the functions required to manipulate them, and a set of meta-data tables. In order to ensure that meta-data remain consistent, operations such as creating and removing a spatial column are carried out through special procedures defined by OpenGIS.

There are two OpenGIS meta-data tables: `SPATIAL_REF_SYS` and `GEOMETRY_COLUMNS`. The `SPATIAL_REF_SYS` table holds the numeric IDs and textual descriptions of coordinate systems used in the spatial database.

### 4.3.1 The SPATIAL\_REF\_SYS Table and Spatial Reference Systems

The `spatial_ref_sys` table is a PostGIS included and OGC compliant database table that lists over 3000 known [spatial reference systems](#) and details needed to transform/reproject between them.

Although the PostGIS `spatial_ref_sys` table contains over 3000 of the more commonly used spatial reference system definitions that can be handled by the proj library, it does not contain all known to man and you can even define your own custom projection if you are familiar with proj4 constructs. Keep in mind that most spatial reference systems are regional and have no meaning when used outside of the bounds they were intended for.

An excellent resource for finding spatial reference systems not defined in the core set is <http://spatialreference.org/>

Some of the more commonly used spatial reference systems are: [4326 - WGS 84 Long Lat](#), [4269 - NAD 83 Long Lat](#), [3395 - WGS 84 World Mercator](#), [2163 - US National Atlas Equal Area](#), Spatial reference systems for each NAD 83, WGS 84 UTM zone - UTM zones are one of the most ideal for measurement, but only cover 6-degree regions.

Various US state plane spatial reference systems (meter or feet based) - usually one or 2 exists per US state. Most of the meter ones are in the core set, but many of the feet based ones or ESRI created ones you will need to pull from [spatialreference.org](#).

For details on determining which UTM zone to use for your area of interest, check out the [utmzone PostGIS plpgsql helper function](#).

The `SPATIAL_REF_SYS` table definition is as follows:

```
CREATE TABLE spatial_ref_sys (
 srid INTEGER NOT NULL PRIMARY KEY,
 auth_name VARCHAR(256),
 auth_srid INTEGER,
 srtext VARCHAR(2048),
 proj4text VARCHAR(2048)
)
```

The `SPATIAL_REF_SYS` columns are as follows:

**SRID** An integer value that uniquely identifies the Spatial Referencing System (SRS) within the database.

**AUTH\_NAME** The name of the standard or standards body that is being cited for this reference system. For example, "EPSG" would be a valid `AUTH_NAME`.

**AUTH\_SRID** The ID of the Spatial Reference System as defined by the Authority cited in the `AUTH_NAME`. In the case of EPSG, this is where the EPSG projection code would go.

**SRTEXT** The Well-Known Text representation of the Spatial Reference System. An example of a WKT SRS representation is:

```
PROJCS["NAD83 / UTM Zone 10N",
 GEOGCS["NAD83",
 DATUM["North_American_Datum_1983",
 SPHEROID["GRS 1980",6378137,298.257222101]
],
 PRIMEM["Greenwich",0],
 UNIT["degree",0.0174532925199433]
],
 PROJECTION["Transverse_Mercator"],
 PARAMETER["latitude_of_origin",0],
 PARAMETER["central_meridian",-123],
 PARAMETER["scale_factor",0.9996],
 PARAMETER["false_easting",500000],
 PARAMETER["false_northing",0],
 UNIT["metre",1]
]
```

For a listing of EPSG projection codes and their corresponding WKT representations, see <http://www.opengeospatial.org/>. For a discussion of WKT in general, see the OpenGIS "Coordinate Transformation Services Implementation Specification" at <http://www.opengeospatial.org/standards>. For information on the European Petroleum Survey Group (EPSG) and their database of spatial reference systems, see <http://www.epsg.org>.

**PROJ4TEXT** PostGIS uses the Proj4 library to provide coordinate transformation capabilities. The PROJ4TEXT column contains the Proj4 coordinate definition string for a particular SRID. For example:

```
+proj=utm +zone=10 +ellps=clrk66 +datum=NAD27 +units=m
```

For more information about, see the Proj4 web site at <http://trac.osgeo.org/proj/>. The `spatial_ref_sys.sql` file contains both SRTEXT and PROJ4TEXT definitions for all EPSG projections.

### 4.3.2 The GEOMETRY\_COLUMNS VIEW

In versions of PostGIS prior to 2.0.0, `geometry_columns` was a table that could be directly edited, and sometimes got out of synch with the actual definition of the geometry columns. In PostGIS 2.0.0, `GEOMETRY_COLUMNS` became a view with the same front-facing structure as prior versions, but reading from database system catalogs. Its structure is as follows:

```
\d geometry_columns
```

| Column                         | Type                                | Modifiers |
|--------------------------------|-------------------------------------|-----------|
| <code>f_table_catalog</code>   | <code>character varying(256)</code> |           |
| <code>f_table_schema</code>    | <code>character varying(256)</code> |           |
| <code>f_table_name</code>      | <code>character varying(256)</code> |           |
| <code>f_geometry_column</code> | <code>character varying(256)</code> |           |
| <code>coord_dimension</code>   | <code>integer</code>                |           |
| <code>srid</code>              | <code>integer</code>                |           |
| <code>type</code>              | <code>character varying(30)</code>  |           |

The column meanings have not changed from prior versions and are:

**F\_TABLE\_CATALOG, F\_TABLE\_SCHEMA, F\_TABLE\_NAME** The fully qualified name of the feature table containing the geometry column. Note that the terms "catalog" and "schema" are Oracle-ish. There is not PostgreSQL analogue of "catalog" so that column is left blank -- for "schema" the PostgreSQL schema name is used (`public` is the default).

**F\_GEOMETRY\_COLUMN** The name of the geometry column in the feature table.

**COORD\_DIMENSION** The spatial dimension (2, 3 or 4 dimensional) of the column.

**SRID** The ID of the spatial reference system used for the coordinate geometry in this table. It is a foreign key reference to the `SPATIAL_REF_SYS`.

**TYPE** The type of the spatial object. To restrict the spatial column to a single type, use one of: `POINT`, `LINestring`, `POLYGON`, `MULTIPOINT`, `MULTILINestring`, `MULTIPOLYGON`, `GEOMETRYCOLLECTION` or corresponding XYM versions `POINTM`, `LINestringM`, `POLYGONM`, `MULTIPOINTM`, `MULTILINestringM`, `MULTIPOLYGONM`, `GEOMETRYCOLLECTIONM`. For heterogeneous (mixed-type) collections, you can use "GEOMETRY" as the type.

#### Note

This attribute is (probably) not part of the OpenGIS specification, but is required for ensuring type homogeneity.

### 4.3.3 Creating a Spatial Table

Creating a table with spatial data, can be done in one step. As shown in the following example which creates a roads table with a 2D linestring geometry column in WGS84 long lat

```
CREATE TABLE ROADS (ID int4
, ROAD_NAME varchar(25), geom geometry(LINestring,4326));
```

We can add additional columns using standard ALTER TABLE command as we do in this next example where we add a 3-D linestring.

```
ALTER TABLE roads ADD COLUMN geom2 geometry(LINESTRINGZ,4326);
```

For backwards compability, you can still create a spatial table in two stages using the management functions.

- Create a normal non-spatial table.

For example: **CREATE TABLE ROADS ( ID int4, ROAD\_NAME varchar(25) )**

- Add a spatial column to the table using the OpenGIS "AddGeometryColumn" function. Refer to [AddGeometryColumn](#) for more details.

The syntax is:

```
AddGeometryColumn (
 <schema_name>,
 <table_name>,
 <column_name>,
 <srid>,
 <type>,
 <dimension>
)
```

Or, using current schema:

```
AddGeometryColumn (
 <table_name>,
 <column_name>,
 <srid>,
 <type>,
 <dimension>
)
```

Example1: **SELECT AddGeometryColumn('public', 'roads', 'geom', 423, 'LINESTRING', 2)**

Example2: **SELECT AddGeometryColumn( 'roads', 'geom', 423, 'LINESTRING', 2)**

Here is an example of SQL used to create a table and add a spatial column (assuming that an SRID of 128 exists already):

```
CREATE TABLE parks (
 park_id INTEGER,
 park_name VARCHAR,
 park_date DATE,
 park_type VARCHAR
);
SELECT AddGeometryColumn('parks', 'park_geom', 128, 'MULTIPOLYGON', 2);
```

Here is another example, using the generic "geometry" type and the undefined SRID value of 0:

```
CREATE TABLE roads (
 road_id INTEGER,
 road_name VARCHAR
);
SELECT AddGeometryColumn('roads', 'roads_geom', 0, 'GEOMETRY', 3);
```

#### 4.3.4 Manually Registering Geometry Columns in geometry\_columns

The AddGeometryColumn() approach creates a geometry column of specified type. This type and dimension are queryable from the geometry\_columns view. Starting with PostGIS 2.0, geometry\_columns is no longer editable and all geometry columns are autoregistered.

If your geometry columns were created as generic in a table or view and no constraints applied, they will not have a dimension, type or srid in geometry\_columns views, but will still be listed.

Two of the cases where this may happen, but you can't use AddGeometryColumn, is in the case of SQL Views and bulk inserts. For bulk insert case, you can correct the registration in the geometry\_columns table by constraining the column or doing an alter table. For views, you could expose using a CAST operation. Note in PostGIS 2.0+ if your column is typmod based, the creation process would register it correctly, so no need to do anything. Also views that have no spatial function applied to the geometry will register the same as the underlying table geometry column.

```
--Lets say you have a view created like this
CREATE VIEW public.vwmytablemercator AS
 SELECT gid, ST_Transform(geom,3395) As geom, f_name
 FROM public.mytable;

-- For it to register correctly in PostGIS 2.0+
-- You need to cast the geometry
--
DROP VIEW public.vwmytablemercator;
CREATE VIEW public.vwmytablemercator AS
 SELECT gid, ST_Transform(geom,3395)::geometry(Geometry, 3395) As geom, f_name
 FROM public.mytable;

-- If you know the geometry type for sure is a 2D POLYGON then you could do
DROP VIEW public.vwmytablemercator;
CREATE VIEW public.vwmytablemercator AS
 SELECT gid, ST_Transform(geom,3395)::geometry(Polygon, 3395) As geom, f_name
 FROM public.mytable;
```

```
--Lets say you created a derivative table by doing a bulk insert
SELECT poi.gid, poi.geom, citybounds.city_name
INTO myschema.my_special_pois
FROM poi INNER JOIN citybounds ON ST_Intersects(citybounds.geom, poi.geom);

--Create 2d index on new table
CREATE INDEX idx_myschema_myspecialpois_geom_gist
 ON myschema.my_special_pois USING gist(geom);

-- If your points are 3D points or 3M points,
-- then you might want to create an nd index instead of a 2d index
-- like so
CREATE INDEX my_special_pois_geom_gist_nd
 ON my_special_pois USING gist(geom gist_geometry_ops_nd);

--To manually register this new table's geometry column in geometry_columns
-- Note that this approach will work for both PostGIS 2.0+ and PostGIS 1.4+
-- For PostGIS 2.0 it will also change the underlying structure of the table to
-- to make the column typmod based.
-- For PostGIS prior to 2.0, this technique can also be used to register views
SELECT populate_geometry_columns('myschema.my_special_pois'::regclass);

--If you are using PostGIS 2.0 and for whatever reason, you
-- you need the old constraint based definition behavior
-- (such as case of inherited tables where all children do not have the same type and srid)
-- set new optional use_typmod argument to false
SELECT populate_geometry_columns('myschema.my_special_pois'::regclass, false);
```

Although the old-constraint based method is still supported, a constraint-based geometry column used directly in a view, will not register correctly in geometry\_columns, as will a typmod one. In this example we define a column using typmod and another using constraints.

```
CREATE TABLE pois_ny(gid SERIAL PRIMARY KEY
 , poi_name text, cat varchar(20)
```

```
, geom geometry(POINT,4326));
SELECT AddGeometryColumn('pois_ny', 'geom_2160', 2160, 'POINT', 2, false);
```

If we run in psql

```
\d pois_ny;
```

We observe they are defined differently -- one is typmod, one is constraint

```
Table "public.pois_ny"
Column | Type | Modifiers
-----+-----+-----
gid | integer | not null default nextval('pois_ny_gid_seq'::regclass)
poi_name | text |
cat | character varying(20) |
geom | geometry(Point,4326) |
geom_2160 | geometry |
Indexes:
 "pois_ny_pkey" PRIMARY KEY, btree (gid)
Check constraints:
 "enforce_dims_geom_2160" CHECK (st_ndims(geom_2160) = 2)
 "enforce_geotype_geom_2160" CHECK (geometrytype(geom_2160) = 'POINT'::text
 OR geom_2160 IS NULL)
 "enforce_srid_geom_2160" CHECK (st_srid(geom_2160) = 2160)
```

In geometry\_columns, they both register correctly

```
SELECT f_table_name, f_geometry_column, srid, type
FROM geometry_columns
WHERE f_table_name = 'pois_ny';
```

```
f_table_name | f_geometry_column | srid | type
-----+-----+-----+-----
pois_ny | geom | 4326 | POINT
pois_ny | geom_2160 | 2160 | POINT
```

However -- if we were to create a view like this

```
CREATE VIEW vw_pois_ny_parks AS
SELECT *
FROM pois_ny
WHERE cat='park';

SELECT f_table_name, f_geometry_column, srid, type
FROM geometry_columns
WHERE f_table_name = 'vw_pois_ny_parks';
```

The typmod based geom view column registers correctly, but the constraint based one does not.

```
f_table_name | f_geometry_column | srid | type
-----+-----+-----+-----
vw_pois_ny_parks | geom | 4326 | POINT
vw_pois_ny_parks | geom_2160 | 0 | GEOMETRY
```

This may change in future versions of PostGIS, but for now To force the constraint based view column to register correctly, we need to do this:

```
DROP VIEW vw_pois_ny_parks;
CREATE VIEW vw_pois_ny_parks AS
SELECT gid, poi_name, cat
```

```

, geom
, geom_2160::geometry(POINT,2160) As geom_2160
FROM pois_ny
WHERE cat='park';
SELECT f_table_name, f_geometry_column, srid, type
FROM geometry_columns
WHERE f_table_name = 'vw_pois_ny_parks';

```

| f_table_name     | f_geometry_column | srid | type  |
|------------------|-------------------|------|-------|
| vw_pois_ny_parks | geom              | 4326 | POINT |
| vw_pois_ny_parks | geom_2160         | 2160 | POINT |

### 4.3.5 Ensuring OpenGIS compliancy of geometries

PostGIS is compliant with the Open Geospatial Consortium's (OGC) OpenGIS Specifications. As such, many PostGIS methods require, or more accurately, assume that geometries that are operated on are both simple and valid. For example, it does not make sense to calculate the area of a polygon that has a hole defined outside of the polygon, or to construct a polygon from a non-simple boundary line.

According to the OGC Specifications, a *simple* geometry is one that has no anomalous geometric points, such as self intersection or self tangency and primarily refers to 0 or 1-dimensional geometries (i.e. [MULTI]POINT, [MULTI]LINESTRING). Geometry validity, on the other hand, primarily refers to 2-dimensional geometries (i.e. [MULTI]POLYGON) and defines the set of assertions that characterizes a valid polygon. The description of each geometric class includes specific conditions that further detail geometric simplicity and validity.

A POINT is inheritably *simple* as a 0-dimensional geometry object.

MULTIPOINTS are *simple* if no two coordinates (POINTS) are equal (have identical coordinate values).

A LINESTRING is *simple* if it does not pass through the same POINT twice (except for the endpoints, in which case it is referred to as a linear ring and additionally considered closed).

(a)

(b)

(c)

(d)

(a) and (c) are simple LINESSTRINGs, (b) and (d) are not.

A MULTILINESTRING is *simple* only if all of its elements are simple and the only intersection between any two elements occurs at POINTs that are on the boundaries of both elements.

(e)

(f)

(g)

(e) and (f) are simple MULTILINESTRINGs, (g) is not.

By definition, a POLYGON is always *simple*. It is *valid* if no two rings in the boundary (made up of an exterior ring and interior rings) cross. The boundary of a POLYGON may intersect at a POINT but only as a tangent (i.e. not on a line). A POLYGON may not have cut lines or spikes and the interior rings must be contained entirely within the exterior ring.

**(h)** and **(i)** are valid **POLYGONS**, **(j-m)** cannot be represented as single **POLYGONS**, but **(j)** and **(m)** could be represented as a valid **MULTIPOLYGON**.

A **MULTIPOLYGON** is *valid* if and only if all of its elements are valid and the interiors of no two elements intersect. The boundaries of any two elements may touch, but only at a finite number of **POINTS**.

(n)

(o)

(n) and (o) are not valid MULTIPOLYGONS. (p), however, is valid.

Most of the functions implemented by the GEOS library rely on the assumption that your geometries are valid as specified by the OpenGIS Simple Feature Specification. To check simplicity or validity of geometries you can use the [ST\\_IsSimple\(\)](#) and [ST\\_IsValid\(\)](#)

```
-- Typically, it doesn't make sense to check
-- for validity on linear features since it will always return TRUE.
-- But in this example, PostGIS extends the definition of the OGC IsValid
-- by returning false if a LineString has less than 2 *distinct* vertices.
gisdb=# SELECT
 ST_IsValid('LINESTRING(0 0, 1 1)'),
 ST_IsValid('LINESTRING(0 0, 0 0, 0 0)');

 st_isvalid | st_isvalid
-----+-----
 t | f
```

By default, PostGIS does not apply this validity check on geometry input, because testing for validity needs lots of CPU time for complex geometries, especially polygons. If you do not trust your data sources, you can manually enforce such a check to your tables by adding a check constraint:

```
ALTER TABLE mytable
 ADD CONSTRAINT geometry_valid_check
 CHECK (ST_IsValid(the_geom));
```

If you encounter any strange error messages such as "GEOS Intersection() threw an error!" or "JTS Intersection() threw an error!" when calling PostGIS functions with valid input geometries, you likely found an error in either PostGIS or one of the libraries it uses, and you should contact the PostGIS developers. The same is true if a PostGIS function returns an invalid geometry for valid input.

#### Note

Strictly compliant OGC geometries cannot have Z or M values. The [ST\\_IsValid\(\)](#) function won't consider higher dimensioned geometries invalid! Invocations of [AddGeometryColumn\(\)](#) will add a constraint checking geometry dimensions, so it is enough to specify 2 there.

### 4.3.6 Dimensionally Extended 9 Intersection Model (DE-9IM)

It is sometimes the case that the typical spatial predicates (`ST_Contains`, `ST_Crosses`, `ST_Intersects`, `ST_Touches`, ...) are insufficient in and of themselves to adequately provide that desired spatial filter.

For example, consider a linear dataset representing a road network. It may be the task of a GIS analyst to identify all road segments that cross each other, not at a point, but on a line, perhaps invalidating some business rule. In this case, `ST_Crosses` does not adequately provide the necessary spatial filter since, for linear features, it returns `true` only where they cross at a point.

One two-step solution might be to first perform the actual intersection (`ST_Intersection`) of pairs of road segments that spatially intersect (`ST_Intersects`), and then compare the intersection's `ST_GeometryType` with 'LINESTRING' (properly dealing with cases that return `GEOMETRYCOLLECTIONS` of `[MULTI]POINTS`, `[MULTI]LINESTRINGs`, etc.). A more elegant / faster solution may indeed be desirable.

A second [theoretical] example may be that of a GIS analyst trying to locate all wharfs or docks that intersect a lake's boundary on a line and where only one end of the wharf is up on shore. In other words, where a wharf is within, but not completely within a lake, intersecting the boundary of a lake on a line, and where the wharf's endpoints are both completely within and on the boundary of the lake. The analyst may need to use a combination of spatial predicates to isolate the sought after features:

- `ST_Contains(lake, wharf) = TRUE`
- `ST_ContainsProperly(lake, wharf) = FALSE`
- `ST_GeometryType(ST_Intersection(wharf, lake)) = 'LINESTRING'`
- `ST_NumGeometries(ST_Multi(ST_Intersection(ST_Boundary(wharf), ST_Boundary(lake)))) = 1`  
... (needless to say, this could get quite complicated)

So enters the Dimensionally Extended 9 Intersection Model, or DE-9IM for short.

#### 4.3.6.1 Theory

According to the [OpenGIS Simple Features Implementation Specification for SQL](#), "the basic approach to comparing two geometries is to make pair-wise tests of the intersections between the Interiors, Boundaries and Exteriors of the two geometries and to classify the relationship between the two geometries based on the entries in the resulting 'intersection' matrix."

##### Boundary

The boundary of a geometry is the set of geometries of the next lower dimension. For POINTs, which have a dimension of 0, the boundary is the empty set. The boundary of a LINESTRING are the two endpoints. For POLYGONS, the boundary is the linework that make up the exterior and interior rings.

##### Interior

The interior of a geometry are those points of a geometry that are left when the boundary is removed. For POINTs, the interior is the POINT itself. The interior of a LINESTRING are the set of real points between the endpoints. For POLYGONS, the interior is the areal surface inside the polygon.

##### Exterior

The exterior of a geometry is the universe, an areal surface, not on the interior or boundary of the geometry.

Given geometry  $a$ , where the  $I(a)$ ,  $B(a)$ , and  $E(a)$  are the *Interior*, *Boundary*, and *Exterior* of  $a$ , the mathematical representation of the matrix is:

|                 | <b>Interior</b>         | <b>Boundary</b>         | <b>Exterior</b>         |
|-----------------|-------------------------|-------------------------|-------------------------|
| <b>Interior</b> | $dim( I(a) \cap I(b) )$ | $dim( I(a) \cap B(b) )$ | $dim( I(a) \cap E(b) )$ |
| <b>Boundary</b> | $dim( B(a) \cap I(b) )$ | $dim( B(a) \cap B(b) )$ | $dim( B(a) \cap E(b) )$ |
| <b>Exterior</b> | $dim( E(a) \cap I(b) )$ | $dim( E(a) \cap B(b) )$ | $dim( E(a) \cap E(b) )$ |

Where  $dim(a)$  is the dimension of  $a$  as specified by **ST\_Dimension** but has the domain of  $\{0, 1, 2, T, F, *\}$

- 0 => point
- 1 => line
- 2 => area
- T =>  $\{0, 1, 2\}$
- F => empty set
- \* => don't care

Visually, for two overlapping polygonal geometries, this looks like:

|          | Interior                                                                                              | Boundary                                                                                               | Exterior                                                                                                |
|----------|-------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------|
| Interior | <br>$dim(...) = 2$   | <br>$dim(...) = 1$   | <br>$dim(...) = 2$   |
| Boundary | <br>$dim(...) = 1$  | <br>$dim(...) = 0$  | <br>$dim(...) = 1$  |
| Exterior | <br>$dim(...) = 2$ | <br>$dim(...) = 1$ | <br>$dim(...) = 2$ |

Read from left to right and from top to bottom, the dimensional matrix is represented, '212101212'.

A relate matrix that would therefore represent our first example of two lines that intersect on a line would be: '1\*1\*\*\*1\*\*'

```
-- Identify road segments that cross on a line
SELECT a.id
FROM roads a, roads b
WHERE a.id != b.id
AND a.geom && b.geom
AND ST_Relate(a.geom, b.geom, '1*1***1**');
```

A relate matrix that represents the second example of wharfs partly on the lake's shoreline would be '102101FF2'

```
-- Identify wharfs partly on a lake's shoreline
SELECT a.lake_id, b.wharf_id
FROM lakes a, wharfs b
WHERE a.geom && b.geom
AND ST_Relate(a.geom, b.geom, '102101FF2');
```

## 4.4 Loading GIS (Vector) Data

Once you have created a spatial table, you are ready to upload GIS data to the database. Currently, there are two ways to get data into a PostGIS/PostgreSQL database: using formatted SQL statements or using the Shape file loader/dumper.

### 4.4.1 Loading Data Using SQL

If you can convert your data to a text representation, then using formatted SQL might be the easiest way to get your data into PostGIS. As with Oracle and other SQL databases, data can be bulk loaded by piping a large text file full of SQL "INSERT" statements into the SQL terminal monitor.

A data upload file (`roads.sql` for example) might look like this:

```
BEGIN;
INSERT INTO roads (road_id, roads_geom, road_name)
 VALUES (1, ST_GeomFromText('LINESTRING(191232 243118,191108 243242)',-1), 'Jeff Rd');
INSERT INTO roads (road_id, roads_geom, road_name)
 VALUES (2, ST_GeomFromText('LINESTRING(189141 244158,189265 244817)',-1), 'Geordie Rd');
INSERT INTO roads (road_id, roads_geom, road_name)
 VALUES (3, ST_GeomFromText('LINESTRING(192783 228138,192612 229814)',-1), 'Paul St');
INSERT INTO roads (road_id, roads_geom, road_name)
 VALUES (4, ST_GeomFromText('LINESTRING(189412 252431,189631 259122)',-1), 'Graeme Ave');
INSERT INTO roads (road_id, roads_geom, road_name)
 VALUES (5, ST_GeomFromText('LINESTRING(190131 224148,190871 228134)',-1), 'Phil Tce');
INSERT INTO roads (road_id, roads_geom, road_name)
 VALUES (6, ST_GeomFromText('LINESTRING(198231 263418,198213 268322)',-1), 'Dave Cres');
COMMIT;
```

The data file can be piped into PostgreSQL very easily using the "psql" SQL terminal monitor:

```
psql -d [database] -f roads.sql
```

### 4.4.2 shp2pgsql: Using the ESRI Shapefile Loader

The `shp2pgsql` data loader converts ESRI Shape files into SQL suitable for insertion into a PostGIS/PostgreSQL database either in geometry or geography format. The loader has several operating modes distinguished by command line flags:

In addition to the `shp2pgsql` command-line loader, there is an `shp2pgsql-gui` graphical interface with most of the options as the command-line loader, but may be easier to use for one-off non-scripted loading or if you are new to PostGIS. It can also be configured as a plugin to PgAdminIII.

**(claldp) These are mutually exclusive options:**

- c Creates a new table and populates it from the shapefile. *This is the default mode.*
- a Appends data from the Shape file into the database table. Note that to use this option to load multiple files, the files must have the same attributes and same data types.
- d Drops the database table before creating a new table with the data in the Shape file.

- p Only produces the table creation SQL code, without adding any actual data. This can be used if you need to completely separate the table creation and data loading steps.
- ? Display help screen.
- D Use the PostgreSQL "dump" format for the output data. This can be combined with -a, -c and -d. It is much faster to load than the default "insert" SQL format. Use this for very large data sets.
- s [**<FROM\_SRID>**;**>**;**<SRID>**] Creates and populates the geometry tables with the specified SRID. Optionally specifies that the input shapefile uses the given FROM\_SRID, in which case the geometries will be reprojected to the target SRID. FROM\_SRID cannot be specified with -D.
- k Keep identifiers' case (column, schema and attributes). Note that attributes in Shapefile are all UPPERCASE.
- i Coerce all integers to standard 32-bit integers, do not create 64-bit bigints, even if the DBF header signature appears to warrant it.
- I Create a GiST index on the geometry column.
- m -m *a\_file\_name* Specify a file containing a set of mappings of (long) column names to 10 character DBF column names. The content of the file is one or more lines of two names separated by white space and no trailing or leading space. For example:
 

```
COLUMNNAME DBFFIELD1
AVERYLONGCOLUMNNAME DBFFIELD2
```
- S Generate simple geometries instead of MULTI geometries. Will only succeed if all the geometries are actually single (I.E. a MULTIPOLYGON with a single shell, or or a MULTIPOINT with a single vertex).
- t **<dimensionality>** Force the output geometry to have the specified dimensionality. Use the following strings to indicate the dimensionality: 2D, 3DZ, 3DM, 4D.  
If the input has fewer dimensions that specified, the output will have those dimensions filled in with zeroes. If the input has more dimensions that specified, the unwanted dimensions will be stripped.
- w Output WKT format, instead of WKB. Note that this can introduce coordinate drifts due to loss of precision.
- e Execute each statement on its own, without using a transaction. This allows loading of the majority of good data when there are some bad geometries that generate errors. Note that this cannot be used with the -D flag as the "dump" format always uses a transaction.
- W **<encoding>** Specify encoding of the input data (dbf file). When used, all attributes of the dbf are converted from the specified encoding to UTF8. The resulting SQL output will contain a SET CLIENT\_ENCODING to UTF8 command, so that the backend will be able to reconvert from UTF8 to whatever encoding the database is configured to use internally.
- N **<policy>** NULL geometries handling policy (insert\*,skip,abort)
- n -n Only import DBF file. If your data has no corresponding shapefile, it will automatically switch to this mode and load just the dbf. So setting this flag is only needed if you have a full shapefile set, and you only want the attribute data and no geometry.
- G Use geography type instead of geometry (requires lon/lat data) in WGS84 long lat (SRID=4326)
- T **<tablespace>** Specify the tablespace for the new table. Indexes will still use the default tablespace unless the -X parameter is also used. The PostgreSQL documentation has a good description on when to use custom tablespaces.
- X **<tablespace>** Specify the tablespace for the new table's indexes. This applies to the primary key index, and the GIST spatial index if -I is also used.

An example session using the loader to create an input file and uploading it might look like this:

```
shp2pgsql -c -D -s 4269 -i -I shaperoads.shp myschema.roadstable > roads.sql
psql -d roadsdb -f roads.sql
```

A conversion and upload can be done all in one step using UNIX pipes:

```
shp2pgsql shaperoads.shp myschema.roadstable | psql -d roadsdb
```

## 4.5 Retrieving GIS Data

Data can be extracted from the database using either SQL or the Shape file loader/dumper. In the section on SQL we will discuss some of the operators available to do comparisons and queries on spatial tables.

### 4.5.1 Using SQL to Retrieve Data

The most straightforward means of pulling data out of the database is to use a SQL select query to reduce the number of RECORDS and COLUMNS returned and dump the resulting columns into a parsable text file:

```
db=# SELECT road_id, ST_AsText(road_geom) AS geom, road_name FROM roads;
```

```
road_id | geom | road_name
-----+-----+-----
 1 | LINESTRING(191232 243118,191108 243242) | Jeff Rd
 2 | LINESTRING(189141 244158,189265 244817) | Geordie Rd
 3 | LINESTRING(192783 228138,192612 229814) | Paul St
 4 | LINESTRING(189412 252431,189631 259122) | Graeme Ave
 5 | LINESTRING(190131 224148,190871 228134) | Phil Tce
 6 | LINESTRING(198231 263418,198213 268322) | Dave Cres
 7 | LINESTRING(218421 284121,224123 241231) | Chris Way
(6 rows)
```

However, there will be times when some kind of restriction is necessary to cut down the number of fields returned. In the case of attribute-based restrictions, just use the same SQL syntax as normal with a non-spatial table. In the case of spatial restrictions, the following operators are available/useful:

**&&** This operator tells whether the bounding box of one geometry intersects the bounding box of another.

**ST\_OrderingEquals** This tests whether two geometries are geometrically identical. For example, if 'POLYGON((0 0,1 1,1 0,0 0))' is the same as 'POLYGON((0 0,1 1,1 0,0 0))' (it is).

**=** This operator is a little more naive, it only tests whether the bounding boxes of two geometries are the same.

Next, you can use these operators in queries. Note that when specifying geometries and boxes on the SQL command line, you must explicitly turn the string representations into geometries by using the "ST\_GeomFromText()" function. The 312 is a fictitious spatial reference system that matches our data. So, for example:

```
SELECT road_id, road_name
FROM roads
WHERE ST_OrderingEquals(roads_geom , ST_GeomFromText('LINESTRING(191232 243118,191108 243242)',312)) ;
```

The above query would return the single record from the "ROADS\_GEOM" table in which the geometry was equal to that value.

When using the "&&" operator, you can specify either a BOX3D as the comparison feature or a GEOMETRY. When you specify a GEOMETRY, however, its bounding box will be used for the comparison.

```
SELECT road_id, road_name
FROM roads
WHERE roads_geom && ST_GeomFromText('POLYGON((...))',312);
```

The above query will use the bounding box of the polygon for comparison purposes.

The most common spatial query will probably be a "frame-based" query, used by client software, like data browsers and web mappers, to grab a "map frame" worth of data for display. Using a "BOX3D" object for the frame, such a query looks like this:

```
SELECT ST_AsText(roads_geom) AS geom
FROM roads
WHERE
roads_geom && ST_MakeEnvelope(191232, 243117,191232, 243119,312);
```

Note the use of the SRID 312, to specify the projection of the envelope.

## 4.5.2 Using the Dumper

The `pgsql2shp` table dumper connects directly to the database and converts a table (possibly defined by a query) into a shape file. The basic syntax is:

```
pgsql2shp [<options>] <database> [<schema>.]<table>
```

```
pgsql2shp [<options>] <database> <query>
```

The commandline options are:

- f <filename>** Write the output to a particular filename.
- h <host>** The database host to connect to.
- p <port>** The port to connect to on the database host.
- P <password>** The password to use when connecting to the database.
- u <user>** The username to use when connecting to the database.
- g <geometry column>** In the case of tables with multiple geometry columns, the geometry column to use when writing the shape file.
- b** Use a binary cursor. This will make the operation faster, but will not work if any NON-geometry attribute in the table lacks a cast to text.
- r** Raw mode. Do not drop the `gid` field, or escape column names.
- d** For backward compatibility: write a 3-dimensional shape file when dumping from old (pre-1.0.0) postgis databases (the default is to write a 2-dimensional shape file in that case). Starting from postgis-1.0.0+, dimensions are fully encoded.
- m filename** Remap identifiers to ten character names. The content of the file is lines of two symbols separated by a single white space and no trailing or leading space: `VERYLONGSYMBOL SHORTONE ANOTHERVERYLONGSYMBOL SHORTER` etc.

## 4.6 Building Indexes

Indexes are what make using a spatial database for large data sets possible. Without indexing, any search for a feature would require a "sequential scan" of every record in the database. Indexing speeds up searching by organizing the data into a search tree which can be quickly traversed to find a particular record. PostgreSQL supports three kinds of indexes by default: B-Tree indexes, R-Tree indexes, and GiST indexes.

- B-Trees are used for data which can be sorted along one axis; for example, numbers, letters, dates. GIS data cannot be rationally sorted along one axis (which is greater, (0,0) or (0,1) or (1,0)?) so B-Tree indexing is of no use for us.
- R-Trees break up data into rectangles, and sub-rectangles, and sub-sub rectangles, etc. R-Trees are used by some spatial databases to index GIS data, but the PostgreSQL R-Tree implementation is not as robust as the GiST implementation.
- GiST (Generalized Search Trees) indexes break up data into "things to one side", "things which overlap", "things which are inside" and can be used on a wide range of data-types, including GIS data. PostGIS uses an R-Tree index implemented on top of GiST to index GIS data.

## 4.6.1 GiST Indexes

GiST stands for "Generalized Search Tree" and is a generic form of indexing. In addition to GIS indexing, GiST is used to speed up searches on all kinds of irregular data structures (integer arrays, spectral data, etc) which are not amenable to normal B-Tree indexing.

Once a GIS data table exceeds a few thousand rows, you will want to build an index to speed up spatial searches of the data (unless all your searches are based on attributes, in which case you'll want to build a normal index on the attribute fields).

The syntax for building a GiST index on a "geometry" column is as follows:

```
CREATE INDEX [indexname] ON [tablename] USING GIST ([geometryfield]);
```

The above syntax will always build a 2D-index. To get the an n-dimensional index supported in PostGIS 2.0+ for the geometry type, you can create one using this syntax

```
CREATE INDEX [indexname] ON [tablename] USING GIST ([geometryfield] gist_geometry_ops_nd);
```

Building a spatial index is a computationally intensive exercise: on tables of around 1 million rows, on a 300MHz Solaris machine, we have found building a GiST index takes about 1 hour. After building an index, it is important to force PostgreSQL to collect table statistics, which are used to optimize query plans:

```
VACUUM ANALYZE [table_name] [(column_name)];
-- This is only needed for PostgreSQL 7.4 installations and below
SELECT UPDATE_GEOMETRY_STATS([table_name], [column_name]);
```

GiST indexes have two advantages over R-Tree indexes in PostgreSQL. Firstly, GiST indexes are "null safe", meaning they can index columns which include null values. Secondly, GiST indexes support the concept of "lossiness" which is important when dealing with GIS objects larger than the PostgreSQL 8K page size. Lossiness allows PostgreSQL to store only the "important" part of an object in an index -- in the case of GIS objects, just the bounding box. GIS objects larger than 8K will cause R-Tree indexes to fail in the process of being built.

## 4.6.2 BRIN Indexes

BRIN stands for "Block Range Index" and is a generic form of indexing that has been introduced in PostgreSQL 9.5. BRIN is a lossy kind of index, and its main usage is to provide a compromise for both read and write performance. Its primary goal is to handle very large tables for which some of the columns have some natural correlation with their physical location within the table. In addition to GIS indexing, BRIN is used to speed up searches on various kinds of regular or irregular data structures (integer, arrays etc).

Once a GIS data table exceeds a few thousand rows, you will want to build an index to speed up spatial searches of the data (unless all your searches are based on attributes, in which case you'll want to build a normal index on the attribute fields). GiST indexes are really performant as long as their size doesn't exceed the amount of RAM available for the database, and as long as you can afford the storage size, and the penalty in write workload. Otherwise, BRIN index can be considered as an alternative.

The idea of a BRIN index is to store only the bounding box englobing all the geometries contained in all the rows in a set of table blocks, called a range. Obviously, this indexing method will only be efficient if the data is physically ordered in a way where the resulting bounding boxes for block ranges will be mutually exclusive. The resulting index will be really small, but will be less efficient than a GiST index in many cases.

Building a BRIN index is way less intensive than building a GiST index. It's quite common to build a BRIN index in more than ten time less than a GiST index would have required. As a BRIN index only store one bounding box for one to many table blocks, it's pretty common to consume up to a thousand time less disk space for this kind of indexes.

You can choose the number of blocks to summarize in a range. If you decrease this number, the index will be bigger but will probably help to get better performance.

The syntax for building a BRIN index on a "geometry" column is as follows:

```
CREATE INDEX [indexname] ON [tablename] USING BRIN ([geometryfield]);
```

The above syntax will always build a 2D-index. To get a 3d-dimensional index, you can create one using this syntax

```
CREATE INDEX [indexname] ON [tablename] USING BRIN ([geometryfield] ↔
 brin_geometry_inclusion_ops_3d);
```

You can also get a 4d-dimensional index using the 4d operator class

```
CREATE INDEX [indexname] ON [tablename] USING BRIN ([geometryfield] ↔
 brin_geometry_inclusion_ops_4d);
```

These above syntaxes will use the default number or block in a range, which is 128. To specify the number of blocks you want to summarise in a range, you can create one using this syntax

```
CREATE INDEX [indexname] ON [tablename] USING BRIN ([geometryfield]) WITH (↔
 pages_per_range = [number]);
```

Also, keep in mind that a BRIN index will only store one index value for a large number of rows. If your table stores geometries with a mixed number of dimensions, it's likely that the resulting index will have poor performance. You can avoid this drop of performance by choosing the operator class whith the least number of dimensions of the stored geometries

Also the "geography" datatype is supported for BRIN indexing. The syntax for building a BRIN index on a "geography" column is as follows:

```
CREATE INDEX [indexname] ON [tablename] USING BRIN ([geographyfield]);
```

The above syntax will always build a 2D-index for geospatial objects on the spheroid.

Currently, just the "inclusion support" is considered here, meaning that just &&, ~ and @ operators can be used for the 2D cases (both for "geometry" and for "geography"), and just the &&& operator can be used for the 3D geometries. There is no support for kNN searches at the moment.

```
VACUUM ANALYZE [table_name] [(column_name)];
-- This is only needed for PostgreSQL 7.4 installations and below
SELECT UPDATE_GEOMETRY_STATS([table_name], [column_name]);
```

### 4.6.3 Using Indexes

Ordinarily, indexes invisibly speed up data access: once the index is built, the query planner transparently decides when to use index information to speed up a query plan. Unfortunately, the PostgreSQL query planner does not optimize the use of GiST indexes well, so sometimes searches which should use a spatial index instead default to a sequence scan of the whole table.

If you find your spatial indexes are not being used (or your attribute indexes, for that matter) there are a couple things you can do:

- Firstly, make sure statistics are gathered about the number and distributions of values in a table, to provide the query planner with better information to make decisions around index usage. For PostgreSQL 7.4 installations and below this is done by running **update\_geometry\_stats([table\_name, column\_name])** (compute distribution) and **VACUUM ANALYZE [table\_name] [column\_name]** (compute number of values). Starting with PostgreSQL 8.0 running **VACUUM ANALYZE** will do both operations. You should regularly vacuum your databases anyways -- many PostgreSQL DBAs have **VACUUM** run as an off-peak cron job on a regular basis.
- If vacuuming does not work, you can force the planner to use the index information by using the **SET ENABLE\_SEQSCAN=OFF** command. You should only use this command sparingly, and only on spatially indexed queries: generally speaking, the planner knows better than you do about when to use normal B-Tree indexes. Once you have run your query, you should consider setting **ENABLE\_SEQSCAN** back on, so that other queries will utilize the planner as normal.

#### Note

As of version 0.6, it should not be necessary to force the planner to use the index with **ENABLE\_SEQSCAN**.

- If you find the planner wrong about the cost of sequential vs index scans try reducing the value of `random_page_cost` in `postgres.conf` or using `SET random_page_cost=#`. Default value for the parameter is 4, try setting it to 1 or 2. Decrementing the value makes the planner more inclined of using Index scans.

## 4.7 Complex Queries

The *raison d'être* of spatial database functionality is performing queries inside the database which would ordinarily require desktop GIS functionality. Using PostGIS effectively requires knowing what spatial functions are available, and ensuring that appropriate indexes are in place to provide good performance. The SRID of 312 used in these examples is purely for demonstration. You should be using a REAL SRID listed in the `spatial_ref_sys` table and one that matches the projection of your data. If your data has no spatial reference system specified, you should be THINKING very thoughtfully why it doesn't and maybe it should. If your reason is because you are modeling something that doesn't have a geographic spatial reference system defined such as the internals of a molecule or a good location on Mars to transport the human race in the event of a nuclear holocaust, then simply leave out the SRID or make one up and insert it in the `spatial_ref_sys` table.

### 4.7.1 Taking Advantage of Indexes

When constructing a query it is important to remember that only the bounding-box-based operators such as `&&` can take advantage of the GiST spatial index. Functions such as `ST_Distance()` cannot use the index to optimize their operation. For example, the following query would be quite slow on a large table:

```
SELECT the_geom
FROM geom_table
WHERE ST_Distance(the_geom, ST_GeomFromText('POINT(100000 200000)', 312)) < 100
```

This query is selecting all the geometries in `geom_table` which are within 100 units of the point (100000, 200000). It will be slow because it is calculating the distance between each point in the table and our specified point, ie. one `ST_Distance()` calculation for each row in the table. We can avoid this by using the `&&` operator to reduce the number of distance calculations required:

```
SELECT the_geom
FROM geom_table
WHERE ST_DWithin(the_geom, ST_MakeEnvelope(90900, 190900, 100100, 200100, 312), 100)
```

This query selects the same geometries, but it does it in a more efficient way. Assuming there is a GiST index on the `the_geom`, the query planner will recognize that it can use the index to reduce the number of rows before calculating the result of the `ST_Distance()` function. Notice that the `ST_MakeEnvelope` geometry which is used in the `&&` operation is a 200 unit square box centered on the original point - this is our "query box". The `&&` operator uses the index to quickly reduce the result set down to only those geometries which have bounding boxes that overlap the "query box". Assuming that our query box is much smaller than the extents of the entire geometry table, this will drastically reduce the number of distance calculations that need to be done.

#### Change in Behavior

As of PostGIS 1.3.0, most of the Geometry Relationship Functions, with the notable exceptions of `ST_Disjoint` and `ST_Relate`, include implicit bounding box overlap operators.

### 4.7.2 Examples of Spatial SQL

The examples in this section will make use of two tables, a table of linear roads, and a table of polygonal municipality boundaries. The table definitions for the `bc_roads` table is:

| Column   | Type              | Description                    |
|----------|-------------------|--------------------------------|
| gid      | integer           | Unique ID                      |
| name     | character varying | Road Name                      |
| the_geom | geometry          | Location Geometry (Linestring) |

The table definition for the `bc_municipality` table is:

| Column   | Type              | Description                 |
|----------|-------------------|-----------------------------|
| gid      | integer           | Unique ID                   |
| code     | integer           | Unique ID                   |
| name     | character varying | City / Town Name            |
| the_geom | geometry          | Location Geometry (Polygon) |

1. *What is the total length of all roads, expressed in kilometers?*

You can answer this question with a very simple piece of SQL:

```
SELECT sum(ST_Length(the_geom))/1000 AS km_roads FROM bc_roads;
```

```
km_roads

70842.1243039643
(1 row)
```

2. *How large is the city of Prince George, in hectares?*

This query combines an attribute condition (on the municipality name) with a spatial calculation (of the area):

```
SELECT
 ST_Area(the_geom)/10000 AS hectares
FROM bc_municipality
WHERE name = 'PRINCE GEORGE';
```

```
hectares

32657.9103824927
(1 row)
```

3. *What is the largest municipality in the province, by area?*

This query brings a spatial measurement into the query condition. There are several ways of approaching this problem, but the most efficient is below:

```
SELECT
 name,
 ST_Area(the_geom)/10000 AS hectares
FROM
 bc_municipality
ORDER BY hectares DESC
LIMIT 1;
```

```
name | hectares
-----+-----
TUMBLER RIDGE | 155020.02556131
(1 row)
```

Note that in order to answer this query we have to calculate the area of every polygon. If we were doing this a lot it would make sense to add an area column to the table that we could separately index for performance. By ordering the results in a descending direction, and then using the PostgreSQL "LIMIT" command we can easily pick off the largest value without using an aggregate function like `max()`.

#### 4. What is the length of roads fully contained within each municipality?

This is an example of a "spatial join", because we are bringing together data from two tables (doing a join) but using a spatial interaction condition ("contained") as the join condition rather than the usual relational approach of joining on a common key:

```
SELECT
 m.name,
 sum(ST_Length(r.the_geom))/1000 as roads_km
FROM
 bc_roads AS r,
 bc_municipality AS m
WHERE
 ST_Contains(m.the_geom,r.the_geom)
GROUP BY m.name
ORDER BY roads_km;
```

| name             | roads_km         |
|------------------|------------------|
| SURREY           | 1539.47553551242 |
| VANCOUVER        | 1450.33093486576 |
| LANGLEY DISTRICT | 833.793392535662 |
| BURNABY          | 773.769091404338 |
| PRINCE GEORGE    | 694.37554369147  |
| ...              |                  |

This query takes a while, because every road in the table is summarized into the final result (about 250K roads for our particular example table). For smaller overlays (several thousand records on several hundred) the response can be very fast.

#### 5. Create a new table with all the roads within the city of Prince George.

This is an example of an "overlay", which takes in two tables and outputs a new table that consists of spatially clipped or cut resultants. Unlike the "spatial join" demonstrated above, this query actually creates new geometries. An overlay is like a turbo-charged spatial join, and is useful for more exact analysis work:

```
CREATE TABLE pg_roads as
SELECT
 ST_Intersection(r.the_geom, m.the_geom) AS intersection_geom,
 ST_Length(r.the_geom) AS rd_orig_length,
 r.*
FROM
 bc_roads AS r,
 bc_municipality AS m
WHERE m.name = 'PRINCE GEORGE' AND ST_Intersects(r.the_geom, m.the_geom);
```

#### 6. What is the length in kilometers of "Douglas St" in Victoria?

```
SELECT
 sum(ST_Length(r.the_geom))/1000 AS kilometers
FROM
 bc_roads r,
 bc_municipality m
WHERE r.name = 'Douglas St' AND m.name = 'VICTORIA'
 AND ST_Contains(m.the_geom, r.the_geom) ;

kilometers

4.89151904172838
(1 row)
```

#### 7. What is the largest municipality polygon that has a hole?

```
SELECT gid, name, ST_Area(the_geom) AS area
FROM bc_municipality
WHERE ST_NRings(the_geom) > 1
ORDER BY area DESC LIMIT 1;
```

```
gid | name | area
-----+-----+-----
12 | SPALLUMCHEEN | 257374619.430216
(1 row)
```

## Chapter 5

# Raster Data Management, Queries, and Applications

### 5.1 Loading and Creating Rasters

For most use cases, you will create PostGIS rasters by loading existing raster files using the packaged `raster2pgsql` raster loader.

#### 5.1.1 Using `raster2pgsql` to load rasters

The `raster2pgsql` is a raster loader executable that loads GDAL supported raster formats into sql suitable for loading into a PostGIS raster table. It is capable of loading folders of raster files as well as creating overviews of rasters.

Since the `raster2pgsql` is compiled as part of PostGIS most often (unless you compile your own GDAL library), the raster types supported by the executable will be the same as those compiled in the GDAL dependency library. To get a list of raster types your particular `raster2pgsql` supports use the `-G` switch. These should be the same as those provided by your PostGIS install documented here [ST\\_GDALDrivers](#) if you are using the same `gdal` library for both.

**Note**

The older version of this tool was a python script. The executable has replaced the python script. If you still find the need for the Python script Examples of the python one can be found at [GDAL PostGIS Raster Driver Usage](#). Please note that the `raster2pgsql` python script may not work with future versions of PostGIS raster and is no longer supported.

**Note**

When creating overviews of a specific factor from a set of rasters that are aligned, it is possible for the overviews to not align. Visit <http://trac.osgeo.org/postgis/ticket/1764> for an example where the overviews do not align.

**EXAMPLE USAGE:**

```
raster2pgsql raster_options_go_here raster_file someschema.sometable > out.sql
```

`-?` Display help screen. Help will also display if you don't pass in any arguments.

`-G` Print the supported raster formats.

**(claldlp) These are mutually exclusive options:**

- c Create new table and populate it with raster(s), *this is the default mode*
- a Append raster(s) to an existing table.
- d Drop table, create new one and populate it with raster(s)
- p Prepare mode, only create the table.

#### Raster processing: Applying constraints for proper registering in raster catalogs

- C Apply raster constraints -- srid, pixelsize etc. to ensure raster is properly registered in `raster_columns` view.
- x Disable setting the max extent constraint. Only applied if -C flag is also used.
- r Set the constraints (spatially unique and coverage tile) for regular blocking. Only applied if -C flag is also used.

#### Raster processing: Optional parameters used to manipulate input raster dataset

- s <SRID> Assign output raster with specified SRID. If not provided or is zero, raster's metadata will be checked to determine an appropriate SRID.
- b **BAND** Index (1-based) of band to extract from raster. For more than one band index, separate with comma (.). If unspecified, all bands of raster will be extracted.
- t **TILE\_SIZE** Cut raster into tiles to be inserted one per table row. `TILE_SIZE` is expressed as `WIDTHxHEIGHT` or set to the value "auto" to allow the loader to compute an appropriate tile size using the first raster and applied to all rasters.
- P Pad right-most and bottom-most tiles to guarantee that all tiles have the same width and height.
- R, --register Register the raster as a filesystem (out-db) raster.  
Only the metadata of the raster and path location to the raster is stored in the database (not the pixels).
- I **OVERVIEW\_FACTOR** Create overview of the raster. For more than one factor, separate with comma(.). Overview table name follows the pattern `o_overview_factor_table`, where `overview_factor` is a placeholder for numerical overview factor and `table` is replaced with the base table name. Created overview is stored in the database and is not affected by -R. Note that your generated sql file will contain both the main table and overview tables.
- N **NODATA** NODATA value to use on bands without a NODATA value.

#### Optional parameters used to manipulate database objects

- q Wrap PostgreSQL identifiers in quotes
  - f **COLUMN** Specify name of destination raster column, default is 'rast'
  - F Add a column with the name of the file
  - n **COLUMN** Specify the name of the filename column. Implies -F.
  - q Wrap PostgreSQL identifiers in quotes.
  - I Create a GiST index on the raster column.
  - M Vacuum analyze the raster table.
  - k Skip NODATA value checks for each raster band.
  - T **tablespace** Specify the tablespace for the new table. Note that indices (including the primary key) will still use the default tablespace unless the -X flag is also used.
  - X **tablespace** Specify the tablespace for the table's new index. This applies to the primary key and the spatial index if the -I flag is used.
  - Y Use copy statements instead of insert statements.
- e Execute each statement individually, do not use a transaction.
  - E **ENDIAN** Control endianness of generated binary output of raster; specify 0 for XDR and 1 for NDR (default); only NDR output is supported now
  - V **version** Specify version of output format. Default is 0. Only 0 is supported at this time.

An example session using the loader to create an input file and uploading it chunked in 100x100 tiles might look like this:

**Note**

You can leave the schema name out e.g `demelevation` instead of `public.demelevation` and the raster table will be created in the default schema of the database or user

```
raster2pgsql -s 4326 -I -C -M *.tif -F -t 100x100 public.demelevation > elev.sql
psql -d gisdb -f elev.sql
```

A conversion and upload can be done all in one step using UNIX pipes:

```
raster2pgsql -s 4326 -I -C -M *.tif -F -t 100x100 public.demelevation | psql -d gisdb
```

Load rasters Massachusetts state plane meters aerial tiles into a schema called `aerial` and create a full view, 2 and 4 level overview tables, use copy mode for inserting (no intermediary file just straight to db), and `-e` don't force everything in a transaction (good if you want to see data in tables right away without waiting). Break up the rasters into 128x128 pixel tiles and apply raster constraints. Use copy mode instead of table insert. (`-F`) Include a field called `filename` to hold the name of the file the tiles were cut from.

```
raster2pgsql -I -C -e -Y -F -s 26986 -t 128x128 -l 2,4 bostonaerials2008/*.jpg aerials. ↵
 boston | psql -U postgres -d gisdb -h localhost -p 5432
```

--get a list of raster types supported:

```
raster2pgsql -G
```

The `-G` commands outputs a list something like

Available GDAL raster formats:

```

### 5.1.2 Creating rasters using PostGIS raster functions

On many occasions, you'll want to create rasters and raster tables right in the database. There are a plethora of functions to do that. The general steps to follow.

1. Create a table with a raster column to hold the new raster records which can be accomplished with:

```
CREATE TABLE myrasters(rid serial primary key, rast raster);
```

2. There are many functions to help with that goal. If you are creating rasters not as a derivative of other rasters, you will want to start with: [ST\\_MakeEmptyRaster](#), followed by [ST\\_AddBand](#)

You can also create rasters from geometries. To achieve that you'll want to use [ST\\_AsRaster](#) perhaps accompanied with other functions such as [ST\\_Union](#) or [ST\\_MapAlgebraFct](#) or any of the family of other map algebra functions.

There are even many more options for creating new raster tables from existing tables. For example you can create a raster table in a different projection from an existing one using [ST\\_Transform](#)

3. Once you are done populating your table initially, you'll want to create a spatial index on the raster column with something like:

```
CREATE INDEX myrasters_rast_st_convexhull_idx ON myrasters USING gist(ST_ConvexHull(↵
rast));
```

Note the use of [ST\\_ConvexHull](#) since most raster operators are based on the convex hull of the rasters.

#### Note

Pre-2.0 versions of PostGIS raster were based on the envelop rather than the convex hull. For the spatial indexes to work properly you'll need to drop those and replace with convex hull based index.

4. Apply raster constraints using [AddRasterConstraints](#)

## 5.2 Raster Catalogs

There are two raster catalog views that come packaged with PostGIS. Both views utilize information embedded in the constraints of the raster tables. As a result the catalog views are always consistent with the raster data in the tables since the constraints are enforced.

1. `raster_columns` this view catalogs all the raster table columns in your database.
2. `raster_overviews` this view catalogs all the raster table columns in your database that serve as overviews for a finer grained table. Tables of this type are generated when you use the `-l` switch during load.

## 5.2.1 Raster Columns Catalog

The `raster_columns` is a catalog of all raster table columns in your database that are of type raster. It is a view utilizing the constraints on the tables so the information is always consistent even if you restore one raster table from a backup of another database. The following columns exist in the `raster_columns` catalog.

If you created your tables not with the loader or forgot to specify the `-C` flag during load, you can enforce the constraints after the fact using `AddRasterConstraints` so that the `raster_columns` catalog registers the common information about your raster tiles.

- `r_table_catalog` The database the table is in. This will always read the current database.
- `r_table_schema` The database schema the raster table belongs to.
- `r_table_name` raster table
- `r_raster_column` the column in the `r_table_name` table that is of type raster. There is nothing in PostGIS preventing you from having multiple raster columns per table so its possible to have a raster table listed multiple times with a different raster column for each.
- `srid` The spatial reference identifier of the raster. Should be an entry in the Section 4.3.1.
- `scale_x` The scaling between geometric spatial coordinates and pixel. This is only available if all tiles in the raster column have the same `scale_x` and this constraint is applied. Refer to `ST_ScaleX` for more details.
- `scale_y` The scaling between geometric spatial coordinates and pixel. This is only available if all tiles in the raster column have the same `scale_y` and the `scale_y` constraint is applied. Refer to `ST_ScaleY` for more details.
- `blocksize_x` The width (number of pixels across) of each raster tile . Refer to `ST_Width` for more details.
- `blocksize_y` The width (number of pixels down) of each raster tile . Refer to `ST_Height` for more details.
- `same_alignment` A boolean that is true if all the raster tiles have the same alignment . Refer to `ST_SameAlignment` for more details.
- `regular_blocking` If the raster column has the spatially unique and coverage tile constraints, the value with be TRUE. Otherwise, it will be FALSE.
- `num_bands` The number of bands in each tile of your raster set. This is the same information as what is provided by `ST_NumBands`
- `pixel_types` An array defining the pixel type for each band. You will have the same number of elements in this array as you have number of bands. The `pixel_types` are one of the following defined in `ST_BandPixelType`.
- `nodata_values` An array of double precision numbers denoting the `nodata_value` for each band. You will have the same number of elements in this array as you have number of bands. These numbers define the pixel value for each band that should be ignored for most operations. This is similar information provided by `ST_BandNoDataValue`.
- `out_db` An array of boolean flags indicating if the raster bands data is maintained outside the database. You will have the same number of elements in this array as you have number of bands.
- `extent` This is the extent of all the raster rows in your raster set. If you plan to load more data that will change the extent of the set, you'll want to run the `DropRasterConstraints` function before load and then reapply constraints with `AddRasterConstraints` after load.
- `spatial_index` A boolean that is true if raster column has a spatial index.

## 5.2.2 Raster Overviews

`raster_overviews` catalogs information about raster table columns used for overviews and additional information about them that is useful to know when utilizing overviews. Overview tables are cataloged in both `raster_columns` and `raster_overviews` because they are rasters in their own right but also serve an additional special purpose of being a lower resolution caricature of a higher resolution table. These are generated along-side the main raster table when you use the `-1` switch in raster loading or can be generated manually using [AddOverviewConstraints](#).

Overview tables contain the same constraints as other raster tables as well as additional informational only constraints specific to overviews.

### Note

The information in `raster_overviews` does not duplicate the information in `raster_columns`. If you need the information about an overview table present in `raster_columns` you can join the `raster_overviews` and `raster_columns` together to get the full set of information you need.

Two main reasons for overviews are:

1. Low resolution representation of the core tables commonly used for fast mapping zoom-out.
2. Computations are generally faster to do on them than their higher resolution parents because there are fewer records and each pixel covers more territory. Though the computations are not as accurate as the high-res tables they support, they can be sufficient in many rule-of-thumb computations.

The `raster_overviews` catalog contains the following columns of information.

- `o_table_catalog` The database the overview table is in. This will always read the current database.
- `o_table_schema` The database schema the overview raster table belongs to.
- `o_table_name` raster overview table name
- `o_raster_column` the raster column in the overview table.
- `r_table_catalog` The database the raster table that this overview services is in. This will always read the current database.
- `r_table_schema` The database schema the raster table that this overview services belongs to.
- `r_table_name` raster table that this overview services.
- `r_raster_column` the raster column that this overview column services.
- `overview_factor` - this is the pyramid level of the overview table. The higher the number the lower the resolution of the table. `raster2pgsql` if given a folder of images, will compute overview of each image file and load separately. Level 1 is assumed and always the original file. Level 2 is will have each tile represent 4 of the original. So for example if you have a folder of 5000x5000 pixel image files that you chose to chunk 125x125, for each image file your base table will have  $(5000*5000)/(125*125)$  records = 1600, your (l=2) `o_2` table will have  $\text{ceiling}(1600/\text{Power}(2,2)) = 400$  rows, your (l=3) `o_3` will have  $\text{ceiling}(1600/\text{Power}(2,3)) = 200$  rows. If your pixels aren't divisible by the size of your tiles, you'll get some scrap tiles (tiles not completely filled). Note that each overview tile generated by `raster2pgsql` has the same number of pixels as its parent, but is of a lower resolution where each pixel of it represents  $(\text{Power}(2,\text{overview\_factor})$  pixels of the original).

## 5.3 Building Custom Applications with PostGIS Raster

The fact that PostGIS raster provides you with SQL functions to render rasters in known image formats gives you a lot of options for rendering them. For example you can use OpenOffice / LibreOffice for rendering as demonstrated in [Rendering PostGIS Raster graphics with LibreOffice Base Reports](#). In addition you can use a wide variety of languages as demonstrated in this section.

### 5.3.1 PHP Example Outputting using ST\_AsPNG in concert with other raster functions

In this section, we'll demonstrate how to use the PHP PostgreSQL driver and the `ST_AsGDALRaster` family of functions to output band 1,2,3 of a raster to a PHP request stream that can then be embedded in an `img src` html tag.

The sample query demonstrates how to combine a whole bunch of raster functions together to grab all tiles that intersect a particular wgs 84 bounding box and then unions with `ST_Union` the intersecting tiles together returning all bands, transforms to user specified projection using `ST_Transform`, and then outputs the results as a png using `ST_AsPNG`.

You would call the below using

```
http://mywebserver/test_raster.php?srid=2249
```

to get the raster image in Massachusetts state plane feet.

```
<?php
/** contents of test_raster.php */
$conn_str = 'dbname=mydb host=localhost port=5432 user=myuser password=myspw';
$dbconn = pg_connect($conn_str);
header('Content-Type: image/png');
/**If a particular projection was requested use it otherwise use mass state plane meters ←
**/
if (!empty($_REQUEST['srid']) && is_numeric($_REQUEST['srid'])){
 $input_srid = intval($_REQUEST['srid']);
}
else { $input_srid = 26986; }
/** The set bytea_output may be needed for PostgreSQL 9.0+, but not for 8.4 */
$sql = "set bytea_output='escape';
SELECT ST_AsPNG(ST_Transform(
 ST_AddBand(ST_Union(rast,1), ARRAY[ST_Union(rast,2),ST_Union(rast,3)])
 , $input_srid)) As new_rast
FROM aerials.boston
WHERE
 ST_Intersects(rast, ST_Transform(ST_MakeEnvelope(-71.1217, 42.227, -71.1210, ←
 42.218, 4326), 26986))";
$result = pg_query($sql);
$row = pg_fetch_row($result);
pg_free_result($result);
if ($row === false) return;
echo pg_unescape_bytea($row[0]);
?>
```

### 5.3.2 ASP.NET C# Example Outputting using ST\_AsPNG in concert with other raster functions

In this section, we'll demonstrate how to use Npgsql PostgreSQL .NET driver and the `ST_AsGDALRaster` family of functions to output band 1,2,3 of a raster to a PHP request stream that can then be embedded in an `img src` html tag.

You will need the `npgsql` .NET PostgreSQL driver for this exercise which you can get the latest of from <http://npgsql.projects.postgresql.org>. Just download the latest and drop into your ASP.NET bin folder and you'll be good to go.

The sample query demonstrates how to combine a whole bunch of raster functions together to grab all tiles that intersect a particular wgs 84 bounding box and then unions with `ST_Union` the intersecting tiles together returning all bands, transforms to user specified projection using `ST_Transform`, and then outputs the results as a png using `ST_AsPNG`.

This is same example as Section 5.3.1 except implemented in C#.

You would call the below using

```
http://mywebserver/TestRaster.ashx?srid=2249
```

to get the raster image in Massachusetts state plane feet.

```
-- web.config connection string section --
<connectionStrings>
 <add name="DSN"
 connectionString="server=localhost;database=mydb;Port=5432;User Id=myuser;password= ←
 mypwd"/>
</connectionStrings>

// Code for TestRaster.ashx
<%@ WebHandler Language="C#" Class="TestRaster" %>
using System;
using System.Data;
using System.Web;
using Npgsql;

public class TestRaster : IHttpHandler
{
 public void ProcessRequest(HttpContext context)
 {
 context.Response.ContentType = "image/png";
 context.Response.BinaryWrite(GetResults(context));
 }

 public bool IsReusable {
 get { return false; }
 }

 public byte[] GetResults(HttpContext context)
 {
 byte[] result = null;
 NpgsqlCommand command;
 string sql = null;
 int input_srid = 26986;
 try {
 using (NpgsqlConnection conn = new NpgsqlConnection(System.Configuration. ←
 ConfigurationManager.ConnectionStrings["DSN"].ConnectionString)) {
 conn.Open();

 if (context.Request["srid"] != null)
 {
 input_srid = Convert.ToInt32(context.Request["srid"]);
 }
 sql = @"SELECT ST_AsPNG(
 ST_Transform(
 ST_AddBand(
 ST_Union(rast,1), ARRAY[ST_Union(rast,2),ST_Union(rast,3)])
 ,:input_srid)) As new_rast
 FROM aerials.boston
 WHERE
 ST_Intersects(rast,
 ST_Transform(ST_MakeEnvelope(-71.1217, 42.227, ←
 -71.1210, 42.218,4326),26986))";
 command = new NpgsqlCommand(sql, conn);
 command.Parameters.Add(new NpgsqlParameter("input_srid", input_srid));

 result = (byte[]) command.ExecuteScalar();
 conn.Close();
 }
 }
 }
}
```

```

 }
 catch (Exception ex)
 {
 result = null;
 context.Response.Write(ex.Message.Trim());
 }
 return result;
}
}

```

### 5.3.3 Java console app that outputs raster query as Image file

This is a simple java console app that takes a query that returns one image and outputs to specified file.

You can download the latest PostgreSQL JDBC drivers from <http://jdbc.postgresql.org/download.html>

You can compile the following code using a command something like:

```

set env CLASSPATH ../\postgresql-9.0-801.jdbc4.jar
javac SaveQueryImage.java
jar cfm SaveQueryImage.jar Manifest.txt *.class

```

And call it from the command-line with something like

```

java -jar SaveQueryImage.jar "SELECT ST_AsPNG(ST_AsRaster(ST_Buffer(ST_Point(1,5),10, ' ↵
quad_segs=2'),150, 150, '8BUI',100));" "test.png"

```

```

-- Manifest.txt --
Class-Path: postgresql-9.0-801.jdbc4.jar
Main-Class: SaveQueryImage

```

```

// Code for SaveQueryImage.java
import java.sql.Connection;
import java.sql.SQLException;
import java.sql.PreparedStatement;
import java.sql.ResultSet;
import java.io.*;

public class SaveQueryImage {
 public static void main(String[] argv) {
 System.out.println("Checking if Driver is registered with DriverManager.");

 try {
 //java.sql.DriverManager.registerDriver (new org.postgresql.Driver());
 Class.forName("org.postgresql.Driver");
 }
 catch (ClassNotFoundException cnfe) {
 System.out.println("Couldn't find the driver!");
 cnfe.printStackTrace();
 System.exit(1);
 }

 Connection conn = null;

 try {
 conn = DriverManager.getConnection("jdbc:postgresql://localhost:5432/mydb","myuser ↵
 ", "mypwd");
 conn.setAutoCommit(false);

 PreparedStatement sGetImg = conn.prepareStatement(argv[0]);

```

```

 ResultSet rs = sGetImg.executeQuery();

FileOutputStream fout;
try
{
 rs.next();
 /** Output to file name requested by user **/
 fout = new FileOutputStream(new File(argv[1]));
 fout.write(rs.getBytes(1));
 fout.close();
}
catch(Exception e)
{
 System.out.println("Can't create file");
 e.printStackTrace();
}

 rs.close();
sGetImg.close();
 conn.close();
}
catch (SQLException se) {
 System.out.println("Couldn't connect: print out a stack trace and exit.");
 se.printStackTrace();
 System.exit(1);
}
}
}

```

### 5.3.4 Use PLPython to dump out images via SQL

This is a plpython stored function that creates a file in the server directory for each record. Requires you have plpython installed. Should work fine with both plpythonu and plpython3u.

```

CREATE OR REPLACE FUNCTION write_file (param_bytes bytea, param_filepath text)
RETURNS text
AS $$
f = open(param_filepath, 'wb+')
f.write(param_bytes)
return param_filepath
$$ LANGUAGE plpythonu;

```

```

--write out 5 images to the PostgreSQL server in varying sizes
-- note the postgresql daemon account needs to have write access to folder
-- this echos back the file names created;
SELECT write_file(ST_AsPNG(
 ST_AsRaster(ST_Buffer(ST_Point(1,5),j*5, 'quad_segs=2'),150*j, 150*j, '8BUI',100)),
 'C:/temp/slices'|| j || '.png')
FROM generate_series(1,5) As j;

```

```

 write_file

```

```

C:/temp/slices1.png
C:/temp/slices2.png
C:/temp/slices3.png
C:/temp/slices4.png
C:/temp/slices5.png

```

### 5.3.5 Outputting Rasters with PSQL

Sadly PSQL doesn't have easy to use built-in functionality for outputting binaries. This is a bit of a hack that piggy backs on PostgreSQL somewhat legacy large object support. To use first launch your psql commandline connected to your database.

Unlike the python approach, this approach creates the file on your local computer.

```
SELECT oid, lowrite(lo_open(oid, 131072), png) As num_bytes
FROM
(VALUES (lo_create(0),
 ST_AsPNG((SELECT rast FROM aerials.boston WHERE rid=1))
)) As v(oid,png);
-- you'll get an output something like --
 oid | num_bytes
-----+-----
2630819 | 74860

-- next note the oid and do this replacing the c:/test.png to file path location
-- on your local computer
\lo_export 2630819 'C:/temp/aerial_samp.png'

-- this deletes the file from large object storage on db
SELECT lo_unlink(2630819);
```

## Chapter 6

# Using PostGIS Geometry: Building Applications

### 6.1 Using MapServer

The Minnesota MapServer is an internet web-mapping server which conforms to the OpenGIS Web Mapping Server specification.

- The MapServer homepage is at <http://mapserver.org>.
- The OpenGIS Web Map Specification is at <http://www.opengeospatial.org/standards/wms>.

#### 6.1.1 Basic Usage

To use PostGIS with MapServer, you will need to know about how to configure MapServer, which is beyond the scope of this documentation. This section will cover specific PostGIS issues and configuration details.

To use PostGIS with MapServer, you will need:

- Version 0.6 or newer of PostGIS.
- Version 3.5 or newer of MapServer.

MapServer accesses PostGIS/PostgreSQL data like any other PostgreSQL client -- using the `libpq` interface. This means that MapServer can be installed on any machine with network access to the PostGIS server, and use PostGIS as a source of data. The faster the connection between the systems, the better.

1. Compile and install MapServer, with whatever options you desire, including the `--with-postgis` configuration option.
2. In your MapServer map file, add a PostGIS layer. For example:

```
LAYER
 CONNECTIONTYPE postgis
 NAME "widehighways"
 # Connect to a remote spatial database
 CONNECTION "user=dbuser dbname=gisdatabase host=bigserver"
 PROCESSING "CLOSE_CONNECTION=DEFER"
 # Get the lines from the 'geom' column of the 'roads' table
 DATA "geom from roads using srid=4326 using unique gid"
 STATUS ON
 TYPE LINE
 # Of the lines in the extents, only render the wide highways
 FILTER "type = 'highway' and numlanes >= 4"
 CLASS
 # Make the superhighways brighter and 2 pixels wide
```

```

 EXPRESSION ([numlanes] >= 6)
 STYLE
 COLOR 255 22 22
 WIDTH 2
 END
 END
 CLASS
 # All the rest are darker and only 1 pixel wide
 EXPRESSION ([numlanes] < 6)
 STYLE
 COLOR 205 92 82
 END
 END
END

```

In the example above, the PostGIS-specific directives are as follows:

**CONNECTIONTYPE** For PostGIS layers, this is always "postgis".

**CONNECTION** The database connection is governed by the a 'connection string' which is a standard set of keys and values like this (with the default values in <>):

```
user=<username> password=<password> dbname=<username> hostname=<server> port=<5432>
```

An empty connection string is still valid, and any of the key/value pairs can be omitted. At a minimum you will generally supply the database name and username to connect with.

**DATA** The form of this parameter is "<geocolumn> from <tablename> using srid=<srid> using unique <primary key>" where the column is the spatial column to be rendered to the map, the SRID is SRID used by the column and the primary key is the table primary key (or any other uniquely-valued column with an index).

You can omit the "using srid" and "using unique" clauses and MapServer will automatically determine the correct values if possible, but at the cost of running a few extra queries on the server for each map draw.

**PROCESSING** Putting in a CLOSE\_CONNECTION=DEFER if you have multiple layers reuses existing connections instead of closing them. This improves speed. Refer to for [MapServer PostGIS Performance Tips](#) for a more detailed explanation.

**FILTER** The filter must be a valid SQL string corresponding to the logic normally following the "WHERE" keyword in a SQL query. So, for example, to render only roads with 6 or more lanes, use a filter of "num\_lanes >= 6".

3. In your spatial database, ensure you have spatial (GiST) indexes built for any the layers you will be drawing.

```
CREATE INDEX [indexname] ON [tablename] USING GIST ([geometrycolumn]);
```

4. If you will be querying your layers using MapServer you will also need to use the "using unique" clause in your DATA statement.

MapServer requires unique identifiers for each spatial record when doing queries, and the PostGIS module of MapServer uses the unique value you specify in order to provide these unique identifiers. Using the table primary key is the best practice.

## 6.1.2 Frequently Asked Questions

1. *When I use an EXPRESSION in my map file, the condition never returns as true, even though I know the values exist in my table.*

Unlike shape files, PostGIS field names have to be referenced in EXPRESSIONS using *lower case*.

```
EXPRESSION ([numlanes] >= 6)
```

2. *The FILTER I use for my Shape files is not working for my PostGIS table of the same data.*

Unlike shape files, filters for PostGIS layers use SQL syntax (they are appended to the SQL statement the PostGIS connector generates for drawing layers in MapServer).

```
FILTER "type = 'highway' and numlanes >= 4"
```

### 3. My PostGIS layer draws much slower than my Shape file layer, is this normal?

In general, the more features you are drawing into a given map, the more likely it is that PostGIS will be slower than Shape files. For maps with relatively few features (100s), PostGIS will often be faster. For maps with high feature density (1000s), PostGIS will always be slower. If you are finding substantial draw performance problems, it is possible that you have not built a spatial index on your table.

```
postgis# CREATE INDEX geotable_gix ON geotable USING GIST (geocolumn);
postgis# VACUUM ANALYZE;
```

### 4. My PostGIS layer draws fine, but queries are really slow. What is wrong?

For queries to be fast, you must have a unique key for your spatial table and you must have an index on that unique key. You can specify what unique key for mapserver to use with the `USING UNIQUE` clause in your `DATA` line:

```
DATA "geom FROM geotable USING UNIQUE gid"
```

### 5. Can I use "geography" columns (new in PostGIS 1.5) as a source for MapServer layers?

Yes! MapServer understands geography columns as being the same as geometry columns, but always using an SRID of 4326. Just make sure to include a "using srid=4326" clause in your `DATA` statement. Everything else works exactly the same as with geometry.

```
DATA "geog FROM geogtable USING SRID=4326 USING UNIQUE gid"
```

## 6.1.3 Advanced Usage

The `USING` pseudo-SQL clause is used to add some information to help mapserver understand the results of more complex queries. More specifically, when either a view or a subselect is used as the source table (the thing to the right of "FROM" in a `DATA` definition) it is more difficult for mapserver to automatically determine a unique identifier for each row and also the SRID for the table. The `USING` clause can provide mapserver with these two pieces of information as follows:

```
DATA "geom FROM (
 SELECT
 table1.geom AS geom,
 table1.gid AS gid,
 table2.data AS data
 FROM table1
 LEFT JOIN table2
 ON table1.id = table2.id
) AS new_table USING UNIQUE gid USING SRID=4326"
```

**USING UNIQUE <uniqueid>** MapServer requires a unique id for each row in order to identify the row when doing map queries. Normally it identifies the primary key from the system tables. However, views and subselects don't automatically have an known unique column. If you want to use MapServer's query functionality, you need to ensure your view or subselect includes a uniquely valued column, and declare it with `USING UNIQUE`. For example, you could explicitly select nee of the table's primary key values for this purpose, or any other column which is guaranteed to be unique for the result set.

#### Note

"Querying a Map" is the action of clicking on a map to ask for information about the map features in that location. Don't confuse "map queries" with the SQL query in a `DATA` definition.

**USING SRID=<srid>** PostGIS needs to know which spatial referencing system is being used by the geometries in order to return the correct data back to MapServer. Normally it is possible to find this information in the "geometry\_columns" table in the PostGIS database, however, this is not possible for tables which are created on the fly such as subselects and views. So the `USING SRID=` option allows the correct SRID to be specified in the `DATA` definition.

## 6.1.4 Examples

Lets start with a simple example and work our way up. Consider the following MapServer layer definition:

```
LAYER
 CONNECTIONTYPE postgis
 NAME "roads"
 CONNECTION "user=theuser password=thepass dbname=thedb host=theserver"
 DATA "geom from roads"
 STATUS ON
 TYPE LINE
 CLASS
 STYLE
 COLOR 0 0 0
 END
 END
END
```

This layer will display all the road geometries in the roads table as black lines.

Now lets say we want to show only the highways until we get zoomed in to at least a 1:100000 scale - the next two layers will achieve this effect:

```
LAYER
 CONNECTIONTYPE postgis
 CONNECTION "user=theuser password=thepass dbname=thedb host=theserver"
 PROCESSING "CLOSE_CONNECTION=DEFER"
 DATA "geom from roads"
 MINSCALE 100000
 STATUS ON
 TYPE LINE
 FILTER "road_type = 'highway'"
 CLASS
 COLOR 0 0 0
 END
END
LAYER
 CONNECTIONTYPE postgis
 CONNECTION "user=theuser password=thepass dbname=thedb host=theserver"
 PROCESSING "CLOSE_CONNECTION=DEFER"
 DATA "geom from roads"
 MAXSCALE 100000
 STATUS ON
 TYPE LINE
 CLASSITEM road_type
 CLASS
 EXPRESSION "highway"
 STYLE
 WIDTH 2
 COLOR 255 0 0
 END
 END
 CLASS
 STYLE
 COLOR 0 0 0
 END
 END
END
```

The first layer is used when the scale is greater than 1:100000, and displays only the roads of type "highway" as black lines. The FILTER option causes only roads of type "highway" to be displayed.

The second layer is used when the scale is less than 1:100000, and will display highways as double-thick red lines, and other roads as regular black lines.

So, we have done a couple of interesting things using only MapServer functionality, but our DATA SQL statement has remained simple. Suppose that the name of the road is stored in another table (for whatever reason) and we need to do a join to get it and label our roads.

```
LAYER
 CONNECTIONTYPE postgis
 CONNECTION "user=theuser password=thepass dbname=thedb host=theserver"
 DATA "geom FROM (SELECT roads.gid AS gid, roads.geom AS geom,
 road_names.name as name FROM roads LEFT JOIN road_names ON
 roads.road_name_id = road_names.road_name_id)
 AS named_roads USING UNIQUE gid USING SRID=4326"
 MAXSCALE 20000
 STATUS ON
 TYPE ANNOTATION
 LABELITEM name
 CLASS
 LABEL
 ANGLE auto
 SIZE 8
 COLOR 0 192 0
 TYPE truetype
 FONT arial
 END
 END
END
```

This annotation layer adds green labels to all the roads when the scale gets down to 1:20000 or less. It also demonstrates how to use an SQL join in a DATA definition.

## 6.2 Java Clients (JDBC)

Java clients can access PostGIS "geometry" objects in the PostgreSQL database either directly as text representations or using the JDBC extension objects bundled with PostGIS. In order to use the extension objects, the "postgis.jar" file must be in your CLASSPATH along with the "postgresql.jar" JDBC driver package.

```
import java.sql.*;
import java.util.*;
import java.lang.*;
import org.postgis.*;

public class JavaGIS {

public static void main(String[] args) {

 java.sql.Connection conn;

 try {
 /*
 * Load the JDBC driver and establish a connection.
 */
 Class.forName("org.postgresql.Driver");
 String url = "jdbc:postgresql://localhost:5432/database";
 conn = DriverManager.getConnection(url, "postgres", "");
 /*
 * Add the geometry types to the connection. Note that you
 * must cast the connection to the pgsq- specific connection
 * implementation before calling the addDataType() method.
 */
 }
}
```

```

 */
 ((org.postgresql.PGConnection) conn).addDataType("geometry", Class.forName("org.postgis. ←
 PGgeometry"));
 ((org.postgresql.PGConnection) conn).addDataType("box3d", Class.forName("org.postgis. ←
 PGbox3d"));
 /*
 * Create a statement and execute a select query.
 */
 Statement s = conn.createStatement();
 ResultSet r = s.executeQuery("select geom,id from geomtable");
 while(r.next()) {
 /*
 * Retrieve the geometry as an object then cast it to the geometry type.
 * Print things out.
 */
 PGgeometry geom = (PGgeometry)r.getObject(1);
 int id = r.getInt(2);
 System.out.println("Row " + id + ":");
 System.out.println(geom.toString());
 }
 s.close();
 conn.close();
}
catch(Exception e) {
 e.printStackTrace();
}
}
}

```

The "PGgeometry" object is a wrapper object which contains a specific topological geometry object (subclasses of the abstract class "Geometry") depending on the type: Point, LineString, Polygon, MultiPoint, MultiLineString, MultiPolygon.

```

PGgeometry geom = (PGgeometry)r.getObject(1);
if(geom.getType() == Geometry.POLYGON) {
 Polygon pl = (Polygon)geom.getGeometry();
 for(int r = 0; r < pl.numRings(); r++) {
 LinearRing rng = pl.getRing(r);
 System.out.println("Ring: " + r);
 for(int p = 0; p < rng.numPoints(); p++) {
 Point pt = rng.getPoint(p);
 System.out.println("Point: " + p);
 System.out.println(pt.toString());
 }
 }
}
}
}

```

The JavaDoc for the extension objects provides a reference for the various data accessor functions in the geometric objects.

## Chapter 7

# Performance tips

### 7.1 Small tables of large geometries

#### 7.1.1 Problem description

Current PostgreSQL versions (including 9.6) suffer from a query optimizer weakness regarding TOAST tables. TOAST tables are a kind of "extension room" used to store large (in the sense of data size) values that do not fit into normal data pages (like long texts, images or complex geometries with lots of vertices), see [the PostgreSQL Documentation for TOAST](#) for more information).

The problem appears if you happen to have a table with rather large geometries, but not too many rows of them (like a table containing the boundaries of all European countries in high resolution). Then the table itself is small, but it uses lots of TOAST space. In our example case, the table itself had about 80 rows and used only 3 data pages, but the TOAST table used 8225 pages.

Now issue a query where you use the geometry operator `&&` to search for a bounding box that matches only very few of those rows. Now the query optimizer sees that the table has only 3 pages and 80 rows. It estimates that a sequential scan on such a small table is much faster than using an index. And so it decides to ignore the GIST index. Usually, this estimation is correct. But in our case, the `&&` operator has to fetch every geometry from disk to compare the bounding boxes, thus reading all TOAST pages, too.

To see whether you suffer from this issue, use the "EXPLAIN ANALYZE" postgresql command. For more information and the technical details, you can read the thread on the postgres performance mailing list: <http://archives.postgresql.org/pgsql-performance/2005-02/msg00030.php>

and newer thread on PostGIS <https://lists.osgeo.org/pipermail/postgis-devel/2017-June/026209.html>

#### 7.1.2 Workarounds

The PostgreSQL people are trying to solve this issue by making the query estimation TOAST-aware. For now, here are two workarounds:

The first workaround is to force the query planner to use the index. Send "SET enable\_seqscan TO off;" to the server before issuing the query. This basically forces the query planner to avoid sequential scans whenever possible. So it uses the GIST index as usual. But this flag has to be set on every connection, and it causes the query planner to make misestimations in other cases, so you should "SET enable\_seqscan TO on;" after the query.

The second workaround is to make the sequential scan as fast as the query planner thinks. This can be achieved by creating an additional column that "caches" the bbox, and matching against this. In our example, the commands are like:

```
SELECT AddGeometryColumn('myschema', 'mytable', 'bbox', '4326', 'GEOMETRY', '2');
UPDATE mytable SET bbox = ST_Envelope(ST_Force2D(the_geom));
```

Now change your query to use the `&&` operator against `bbox` instead of `geom_column`, like:

```
SELECT geom_column
FROM mytable
WHERE bbox && ST_SetSRID('BOX3D(0 0,1 1) '::box3d,4326);
```

Of course, if you change or add rows to mytable, you have to keep the bbox "in sync". The most transparent way to do this would be triggers, but you also can modify your application to keep the bbox column current or run the UPDATE query above after every modification.

## 7.2 CLUSTERing on geometry indices

For tables that are mostly read-only, and where a single index is used for the majority of queries, PostgreSQL offers the CLUSTER command. This command physically reorders all the data rows in the same order as the index criteria, yielding two performance advantages: First, for index range scans, the number of seeks on the data table is drastically reduced. Second, if your working set concentrates to some small intervals on the indices, you have a more efficient caching because the data rows are spread along fewer data pages. (Feel invited to read the CLUSTER command documentation from the PostgreSQL manual at this point.)

However, currently PostgreSQL does not allow clustering on PostGIS GIST indices because GIST indices simply ignores NULL values, you get an error message like:

```
lwgeom=# CLUSTER my_geom_index ON my_table;
ERROR: cannot cluster when index access method does not handle null values
HINT: You may be able to work around this by marking column "the_geom" NOT NULL.
```

As the HINT message tells you, one can work around this deficiency by adding a "not null" constraint to the table:

```
lwgeom=# ALTER TABLE my_table ALTER COLUMN the_geom SET not null;
ALTER TABLE
```

Of course, this will not work if you in fact need NULL values in your geometry column. Additionally, you must use the above method to add the constraint, using a CHECK constraint like "ALTER TABLE blubb ADD CHECK (geometry is not null);" will not work.

## 7.3 Avoiding dimension conversion

Sometimes, you happen to have 3D or 4D data in your table, but always access it using OpenGIS compliant ST\_AsText() or ST\_AsBinary() functions that only output 2D geometries. They do this by internally calling the ST\_Force2D() function, which introduces a significant overhead for large geometries. To avoid this overhead, it may be feasible to pre-drop those additional dimensions once and forever:

```
UPDATE mytable SET the_geom = ST_Force2D(the_geom);
VACUUM FULL ANALYZE mytable;
```

Note that if you added your geometry column using AddGeometryColumn() there'll be a constraint on geometry dimension. To bypass it you will need to drop the constraint. Remember to update the entry in the geometry\_columns table and recreate the constraint afterwards.

In case of large tables, it may be wise to divide this UPDATE into smaller portions by constraining the UPDATE to a part of the table via a WHERE clause and your primary key or another feasible criteria, and running a simple "VACUUM;" between your UPDATES. This drastically reduces the need for temporary disk space. Additionally, if you have mixed dimension geometries, restricting the UPDATE by "WHERE dimension(the\_geom)>2" skips re-writing of geometries that already are in 2D.

## 7.4 Tuning your configuration

Tuning for PostGIS is much like tuning for any PostgreSQL workload. The only additional note to keep in mind is that geometries and rasters are heavy so memory related optimizations generally have more of an impact on PostGIS than other types of PostgreSQL queries.

For general details about optimizing PostgreSQL, refer to [Tuning your PostgreSQL Server](#).

For PostgreSQL 9.4+ all these can be set at the server level without touching `postgresql.conf` or `postgresql.auto.conf` by using the `ALTER SYSTEM . .` command.

```
ALTER SYSTEM SET work_mem = '256MB';
-- this will force, non-startup configs to take effect for new connections
SELECT pg_reload_conf();
-- show current setting value
-- use SHOW ALL to see all settings
SHOW work_mem;
```

In addition to these settings, PostGIS also has some custom settings which you can find listed in [Section 8.2](#).

### 7.4.1 Startup

These settings are configured in `postgresql.conf`:

#### `constraint_exclusion`

- Default: partition
- This is generally used for table partitioning. The default for this is set to "partition" which is ideal for PostgreSQL 8.4 and above since it will force the planner to only analyze tables for constraint consideration if they are in an inherited hierarchy and not pay the planner penalty otherwise.

#### `shared_buffers`

- Default: ~128MB in PostgreSQL 9.6
- Set to about 25% to 40% of available RAM. On windows you may not be able to set as high.

`max_worker_processes` This setting is only available for PostgreSQL 9.4+. For PostgreSQL 9.6+ this setting has additional importance in that it controls the max number of processes you can have for parallel queries.

- Default: 8
- Sets the maximum number of background processes that the system can support. This parameter can only be set at server start.

### 7.4.2 Runtime

`work_mem` (the memory used for sort operations and complex queries)

- Default: 1-4MB
- Adjust up for large dbs, complex queries, lots of RAM
- Adjust down for many concurrent users or low RAM.
- If you have lots of RAM and few developers:

```
SET work_mem TO '256MB';
```

**maintenance\_work\_mem** (used for VACUUM, CREATE INDEX, etc.)

- Default: 16-64MB
- Generally too low - ties up I/O, locks objects while swapping memory
- Recommend 32MB to 1GB on production servers w/lots of RAM, but depends on the # of concurrent users. If you have lots of RAM and few developers:

```
SET maintenance_work_mem TO '1GB';
```

**max\_parallel\_workers\_per\_gather** This setting is only available for PostgreSQL 9.6+ and will only affect PostGIS 2.3+, since only PostGIS 2.3+ supports parallel queries. If set to higher than 0, then some queries such as those involving relation functions like `ST_Intersects` can use multiple processes and can run more than twice as fast when doing so. If you have a lot of processors to spare, you should change the value of this to as many processors as you have. Also make sure to bump up `max_worker_processes` to at least as high as this number.

- Default: 0
- Sets the maximum number of workers that can be started by a single `Gather` node. Parallel workers are taken from the pool of processes established by `max_worker_processes`. Note that the requested number of workers may not actually be available at run time. If this occurs, the plan will run with fewer workers than expected, which may be inefficient. Setting this value to 0, which is the default, disables parallel query execution.

## Chapter 8

# PostGIS Reference

The functions given below are the ones which a user of PostGIS is likely to need. There are other functions which are required support functions to the PostGIS objects which are not of use to a general user.

**Note**

PostGIS has begun a transition from the existing naming convention to an SQL-MM-centric convention. As a result, most of the functions that you know and love have been renamed using the standard spatial type (ST) prefix. Previous functions are still available, though are not listed in this document where updated functions are equivalent. The non ST\_ functions not listed in this documentation are deprecated and will be removed in a future release so STOP USING THEM.

### 8.1 PostgreSQL PostGIS Geometry/Geography/Box Types

#### 8.1.1 box2d

box2d — A box composed of x min, ymin, xmax, ymax. Often used to return the 2d enclosing box of a geometry.

**Description**

box2d is a spatial data type used to represent the enclosing box of a geometry or set of geometries. ST\_Extent in earlier versions prior to PostGIS 1.4 would return a box2d.

#### 8.1.2 box3d

box3d — A box composed of x min, ymin, zmin, xmax, ymax, zmax. Often used to return the 3d extent of a geometry or collection of geometries.

**Description**

box3d is a postgis spatial data type used to represent the enclosing box of a geometry or set of geometries. ST\_3DExtent returns a box3d object.

**Casting Behavior**

This section lists the automatic as well as explicit casts allowed for this data type

| Cast To  | Behavior  |
|----------|-----------|
| box      | automatic |
| box2d    | automatic |
| geometry | automatic |

### 8.1.3 geometry

geometry — Planar spatial data type.

#### Description

geometry is a fundamental postgis spatial data type used to represent a feature in the Euclidean coordinate system.

#### Casting Behavior

This section lists the automatic as well as explicit casts allowed for this data type

| Cast To   | Behavior  |
|-----------|-----------|
| box       | automatic |
| box2d     | automatic |
| box3d     | automatic |
| bytea     | automatic |
| geography | automatic |
| text      | automatic |

#### See Also

Section [4.1](#)

### 8.1.4 geometry\_dump

geometry\_dump — A spatial datatype with two fields - geom (holding a geometry object) and path[] (a 1-d array holding the position of the geometry within the dumped object.)

#### Description

geometry\_dump is a compound data type consisting of a geometry object referenced by the .geom field and path[] a 1-dimensional integer array (starting at 1 e.g. path[1] to get first element) array that defines the navigation path within the dumped geometry to find this element. It is used by the ST\_Dump\* family of functions as an output type to explode a more complex geometry into its constituent parts and location of parts.

#### See Also

Section [14.6](#)

### 8.1.5 geography

geography — Ellipsoidal spatial data type.

**Description**

geography is a spatial data type used to represent a feature in the round-earth coordinate system.

**Casting Behavior**

This section lists the automatic as well as explicit casts allowed for this data type

| Cast To  | Behavior |
|----------|----------|
| geometry | explicit |

**See Also**

Section [14.4](#), Section [4.2](#)

## 8.2 PostGIS Grand Unified Custom Variables (GUCs)

### 8.2.1 `postgis.backend`

`postgis.backend` — The backend to service a function where GEOS and SFCGAL overlap. Options: `geos` or `sfcgal`. Defaults to `geos`.

**Description**

This GUC is only relevant if you compiled PostGIS with `sfcgal` support. By default `geos` backend is used for functions where both GEOS and SFCGAL have the same named function. This variable allows you to override and make `sfcgal` the backend to service the request.

Availability: 2.1.0

**Examples**

Sets backend just for life of connection

```
set postgis.backend = sfcgal;
```

Sets backend for new connections to database

```
ALTER DATABASE mygisdb SET postgis.backend = sfcgal;
```

**See Also**

Section [8.10](#)

### 8.2.2 `postgis.gdal_datapath`

`postgis.gdal_datapath` — A configuration option to assign the value of GDAL's `GDAL_DATA` option. If not set, the environmentally set `GDAL_DATA` variable is used.

## Description

A PostgreSQL GUC variable for setting the value of GDAL's GDAL\_DATA option. The `postgis.gdal_datapath` value should be the complete physical path to GDAL's data files.

This configuration option is of most use for Windows platforms where GDAL's data files path is not hard-coded. This option should also be set when GDAL's data files are not located in GDAL's expected path.

### Note

This option can be set in PostgreSQL's configuration file `postgresql.conf`. It can also be set by connection or transaction.

---

Availability: 2.2.0

### Note

Additional information about GDAL\_DATA is available at GDAL's [Configuration Options](#).

---

## Examples

Set and reset `postgis.gdal_datapath`

```
SET postgis.gdal_datapath TO '/usr/local/share/gdal.hidden';
SET postgis.gdal_datapath TO default;
```

Setting on windows for a particular database

```
ALTER DATABASE gisdb
SET postgis.gdal_datapath = 'C:/Program Files/PostgreSQL/9.3/gdal-data';
```

## See Also

[PostGIS\\_GDAL\\_Version](#), [ST\\_Transform](#)

## 8.2.3 `postgis.gdal_enabled_drivers`

`postgis.gdal_enabled_drivers` — A configuration option to set the enabled GDAL drivers in the PostGIS environment. Affects the GDAL configuration variable GDAL\_SKIP.

## Description

A configuration option to set the enabled GDAL drivers in the PostGIS environment. Affects the GDAL configuration variable GDAL\_SKIP. This option can be set in PostgreSQL's configuration file: `postgresql.conf`. It can also be set by connection or transaction.

The initial value of `postgis.gdal_enabled_drivers` may also be set by passing the environment variable `POSTGIS_GDAL_ENABLED_DRIVERS` with the list of enabled drivers to the process starting PostgreSQL.

Enabled GDAL specified drivers can be specified by the driver's short-name or code. Driver short-names or codes can be found at [GDAL Raster Formats](#). Multiple drivers can be specified by putting a space between each driver.

---

**Note**

There are three special codes available for `postgis.gdal_enabled_drivers`. The codes are case-sensitive.

- `DISABLE_ALL` disables all GDAL drivers. If present, `DISABLE_ALL` overrides all other values in `postgis.gdal_enabled_drivers`.
- `ENABLE_ALL` enables all GDAL drivers.
- `VSI_CURL` enables GDAL's `/vsicurl/` virtual file system.

When `postgis.gdal_enabled_drivers` is set to `DISABLE_ALL`, attempts to use out-db rasters, `ST_FromGDALRaster()`, `ST_AsGDALRaster()`, `ST_AsTIFF()`, `ST_AsJPEG()` and `ST_AsPNG()` will result in error messages.

Note!**Note**

In the standard PostGIS installation, `postgis.gdal_enabled_drivers` is set to `DISABLE_ALL`.

Note!**Note**

Additional information about `GDAL_SKIP` is available at GDAL's [Configuration Options](#).

Availability: 2.2.0

**Examples**

Set and reset `postgis.gdal_enabled_drivers`

Sets backend for all new connections to database

```
ALTER DATABASE mygisdb SET postgis.gdal_enabled_drivers TO 'GTiff PNG JPEG';
```

Sets default enabled drivers for all new connections to server. Requires super user access and PostgreSQL 9.4+. Also not that database, session, and user settings override this.

```
ALTER SYSTEM SET postgis.gdal_enabled_drivers TO 'GTiff PNG JPEG';
SELECT pg_reload_conf();
```

```
SET postgis.gdal_enabled_drivers TO 'GTiff PNG JPEG';
SET postgis.gdal_enabled_drivers = default;
```

Enable all GDAL Drivers

```
SET postgis.gdal_enabled_drivers = 'ENABLE_ALL';
```

Disable all GDAL Drivers

```
SET postgis.gdal_enabled_drivers = 'DISABLE_ALL';
```

**See Also**

[ST\\_FromGDALRaster](#), [ST\\_AsGDALRaster](#), [ST\\_AsTIFF](#), [ST\\_AsPNG](#), [ST\\_AsJPEG](#), [postgis.enable\\_outdb\\_rasters](#)

## 8.2.4 `postgis.enable_outdb_rasters`

`postgis.enable_outdb_rasters` — A boolean configuration option to enable access to out-db raster bands.

### Description

A boolean configuration option to enable access to out-db raster bands. This option can be set in PostgreSQL's configuration file: `postgresql.conf`. It can also be set by connection or transaction.

The initial value of `postgis.enable_outdb_rasters` may also be set by passing the environment variable `POSTGIS_ENABLE_OUTDB_RASTERS` with a non-zero value to the process starting PostgreSQL.

#### Note

Even if `postgis.enable_outdb_rasters` is `True`, the GUC `postgis.enable_outdb_rasters` determines the accessible raster formats.

#### Note

In the standard PostGIS installation, `postgis.enable_outdb_rasters` is set to `False`.

Availability: 2.2.0

### Examples

Set and reset `postgis.enable_outdb_rasters`

```
SET postgis.enable_outdb_rasters TO True;
SET postgis.enable_outdb_rasters = default;
SET postgis.enable_outdb_rasters = True;
SET postgis.enable_outdb_rasters = False;
```

### See Also

## 8.3 Management Functions

### 8.3.1 `AddGeometryColumn`

`AddGeometryColumn` — Adds a geometry column to an existing table of attributes. By default uses type modifier to define rather than constraints. Pass in `false` for `use_typmod` to get old check constraint based behavior

#### Synopsis

text `AddGeometryColumn`(varchar table\_name, varchar column\_name, integer srid, varchar type, integer dimension, boolean use\_typmod=true);

text `AddGeometryColumn`(varchar schema\_name, varchar table\_name, varchar column\_name, integer srid, varchar type, integer dimension, boolean use\_typmod=true);

text `AddGeometryColumn`(varchar catalog\_name, varchar schema\_name, varchar table\_name, varchar column\_name, integer srid, varchar type, integer dimension, boolean use\_typmod=true);

## Description

Adds a geometry column to an existing table of attributes. The `schema_name` is the name of the table schema. The `srid` must be an integer value reference to an entry in the `SPATIAL_REF_SYS` table. The `type` must be a string corresponding to the geometry type, eg, 'POLYGON' or 'MULTILINESTRING'. An error is thrown if the schemaname doesn't exist (or not visible in the current search\_path) or the specified SRID, geometry type, or dimension is invalid.

### Note

Changed: 2.0.0 This function no longer updates `geometry_columns` since `geometry_columns` is a view that reads from system catalogs. It by default also does not create constraints, but instead uses the built in type modifier behavior of PostgreSQL. So for example building a wgs84 POINT column with this function is now equivalent to: `ALTER TABLE some_table ADD COLUMN geom geometry(Point, 4326);`

Changed: 2.0.0 If you require the old behavior of constraints use the default `use_typmod`, but set it to `false`.

### Note

Changed: 2.0.0 Views can no longer be manually registered in `geometry_columns`, however views built against geometry typmod tables geometries and used without wrapper functions will register themselves correctly because they inherit the typmod behavior of their parent table column. Views that use geometry functions that output other geometries will need to be cast to typmod geometries for these view geometry columns to be registered correctly in `geometry_columns`. Refer to Section 4.3.4.

This method implements the [OpenGIS Simple Features Implementation Specification for SQL 1.1](#).

This function supports 3d and will not drop the z-index.

This method supports Circular Strings and Curves

Enhanced: 2.0.0 `use_typmod` argument introduced. Defaults to creating typmod geometry column instead of constraint-based.

## Examples

```
-- Create schema to hold data
CREATE SCHEMA my_schema;
-- Create a new simple PostgreSQL table
CREATE TABLE my_schema.my_spatial_table (id serial);

-- Describing the table shows a simple table with a single "id" column.
postgis=# \d my_schema.my_spatial_table
 Table "my_schema.my_spatial_table"
 Column | Type | Modifiers
-----+-----+-----
 id | integer | not null default nextval('my_schema.my_spatial_table_id_seq'::regclass)

-- Add a spatial column to the table
SELECT AddGeometryColumn ('my_schema','my_spatial_table','geom',4326,'POINT',2);

-- Add a point using the old constraint based behavior
SELECT AddGeometryColumn ('my_schema','my_spatial_table','geom_c',4326,'POINT',2, false);

--Add a curvepolygon using old constraint behavior
SELECT AddGeometryColumn ('my_schema','my_spatial_table','geomcp_c',4326,'CURVEPOLYGON',2, ←
 false);
```

```
-- Describe the table again reveals the addition of a new geometry columns.
\d my_schema.my_spatial_table
 addgeometrycolumn

my_schema.my_spatial_table.geomcp_c SRID:4326 TYPE:CURVEPOLYGON DIMS:2
(1 row)
```

| Column   | Type                 | Table "my_schema.my_spatial_table" | Modifiers                                                                      |
|----------|----------------------|------------------------------------|--------------------------------------------------------------------------------|
| id       | integer              |                                    | not null default nextval('my_schema. ↵<br>my_spatial_table_id_seq')::regclass) |
| geom     | geometry(Point,4326) |                                    |                                                                                |
| geom_c   | geometry             |                                    |                                                                                |
| geomcp_c | geometry             |                                    |                                                                                |

```
Check constraints:
"enforce_dims_geom_c" CHECK (st_ndims(geom_c) = 2)
"enforce_dims_geomcp_c" CHECK (st_ndims(geomcp_c) = 2)
"enforce_geotype_geom_c" CHECK (geometrytype(geom_c) = 'POINT'::text OR geom_c IS NULL)
"enforce_geotype_geomcp_c" CHECK (geometrytype(geomcp_c) = 'CURVEPOLYGON'::text OR ↵
geomcp_c IS NULL)
"enforce_srid_geom_c" CHECK (st_srid(geom_c) = 4326)
"enforce_srid_geomcp_c" CHECK (st_srid(geomcp_c) = 4326)
```

```
-- geometry_columns view also registers the new columns --
SELECT f_geometry_column As col_name, type, srid, coord_dimension As ndims
FROM geometry_columns
WHERE f_table_name = 'my_spatial_table' AND f_table_schema = 'my_schema';
```

| col_name | type         | srid | ndims |
|----------|--------------|------|-------|
| geom     | Point        | 4326 | 2     |
| geom_c   | Point        | 4326 | 2     |
| geomcp_c | CurvePolygon | 4326 | 2     |

## See Also

[DropGeometryColumn](#), [DropGeometryTable](#), [Section 4.3.2](#), [Section 4.3.4](#)

### 8.3.2 DropGeometryColumn

**DropGeometryColumn** — Removes a geometry column from a spatial table.

#### Synopsis

```
text DropGeometryColumn(varchar table_name, varchar column_name);
text DropGeometryColumn(varchar schema_name, varchar table_name, varchar column_name);
text DropGeometryColumn(varchar catalog_name, varchar schema_name, varchar table_name, varchar column_name);
```

#### Description

Removes a geometry column from a spatial table. Note that `schema_name` will need to match the `f_table_schema` field of the table's row in the `geometry_columns` table.

This method implements the [OpenGIS Simple Features Implementation Specification for SQL 1.1](#).

This function supports 3d and will not drop the z-index.

This method supports Circular Strings and Curves

**Note**

Changed: 2.0.0 This function is provided for backward compatibility. Now that since `geometry_columns` is now a view against the system catalogs, you can drop a geometry column like any other table column using `ALTER TABLE`

**Examples**

```
SELECT DropGeometryColumn ('my_schema', 'my_spatial_table', 'geom');
----RESULT output ---
 dropgeometrycolumn

my_schema.my_spatial_table.geom effectively removed.

-- In PostGIS 2.0+ the above is also equivalent to the standard
-- the standard alter table. Both will deregister from geometry_columns
ALTER TABLE my_schema.my_spatial_table DROP column geom;
```

**See Also**

[AddGeometryColumn](#), [DropGeometryTable](#), [Section 4.3.2](#)

**8.3.3 DropGeometryTable**

`DropGeometryTable` — Drops a table and all its references in `geometry_columns`.

**Synopsis**

```
boolean DropGeometryTable(varchar table_name);
boolean DropGeometryTable(varchar schema_name, varchar table_name);
boolean DropGeometryTable(varchar catalog_name, varchar schema_name, varchar table_name);
```

**Description**

Drops a table and all its references in `geometry_columns`. Note: uses `current_schema()` on schema-aware postgresql installations if schema is not provided.

**Note**

Changed: 2.0.0 This function is provided for backward compatibility. Now that since `geometry_columns` is now a view against the system catalogs, you can drop a table with geometry columns like any other table using `DROP TABLE`

## Examples

```
SELECT DropGeometryTable ('my_schema','my_spatial_table');
----RESULT output ---
my_schema.my_spatial_table dropped.

-- The above is now equivalent to --
DROP TABLE my_schema.my_spatial_table;
```

## 8.3.4 PostGIS\_Full\_Version

PostGIS\_Full\_Version — Reports full postgis version and build configuration infos.

### Synopsis

text **PostGIS\_Full\_Version**();

### Description

Reports full postgis version and build configuration infos. Also informs about synchronization between libraries and scripts suggesting upgrades as needed.

### Examples

```
SELECT PostGIS_Full_Version();
 postgis_full_version

POSTGIS="2.2.0dev r12699" GEOS="3.5.0dev-CAPI-1.9.0 r3989" SFCGAL="1.0.4" PROJ="Rel. 4.8.0, ↵
 6 March 2012"
GDAL="GDAL 1.11.0, released 2014/04/16" LIBXML="2.7.8" LIBJSON="0.12" RASTER
(1 row)
```

## See Also

[Section 2.10](#), [PostGIS\\_GEOS\\_Version](#), [PostGIS\\_Lib\\_Version](#), [PostGIS\\_LibXML\\_Version](#), [PostGIS\\_PROJ\\_Version](#), [PostGIS\\_Version](#)

## 8.3.5 PostGIS\_GEOS\_Version

PostGIS\_GEOS\_Version — Returns the version number of the GEOS library.

### Synopsis

text **PostGIS\_GEOS\_Version**();

### Description

Returns the version number of the GEOS library, or NULL if GEOS support is not enabled.

## Examples

```
SELECT PostGIS_GEOS_Version();
 postgis_geos_version

 3.1.0-CAPI-1.5.0
(1 row)
```

## See Also

[PostGIS\\_Full\\_Version](#), [PostGIS\\_Lib\\_Version](#), [PostGIS\\_LibXML\\_Version](#), [PostGIS\\_PROJ\\_Version](#), [PostGIS\\_Version](#)

### 8.3.6 PostGIS\_LibXML\_Version

`PostGIS_LibXML_Version` — Returns the version number of the libxml2 library.

#### Synopsis

text `PostGIS_LibXML_Version()`;

#### Description

Returns the version number of the LibXML2 library.

Availability: 1.5

## Examples

```
SELECT PostGIS_LibXML_Version();
 postgis_libxml_version

 2.7.6
(1 row)
```

## See Also

[PostGIS\\_Full\\_Version](#), [PostGIS\\_Lib\\_Version](#), [PostGIS\\_PROJ\\_Version](#), [PostGIS\\_GEOS\\_Version](#), [PostGIS\\_Version](#)

### 8.3.7 PostGIS\_Lib\_Build\_Date

`PostGIS_Lib_Build_Date` — Returns build date of the PostGIS library.

#### Synopsis

text `PostGIS_Lib_Build_Date()`;

#### Description

Returns build date of the PostGIS library.

---

## Examples

```
SELECT PostGIS_Lib_Build_Date();
 postgis_lib_build_date

2008-06-21 17:53:21
(1 row)
```

### 8.3.8 PostGIS\_Lib\_Version

PostGIS\_Lib\_Version — Returns the version number of the PostGIS library.

#### Synopsis

```
text PostGIS_Lib_Version();
```

#### Description

Returns the version number of the PostGIS library.

#### Examples

```
SELECT PostGIS_Lib_Version();
 postgis_lib_version

1.3.3
(1 row)
```

#### See Also

[PostGIS\\_Full\\_Version](#), [PostGIS\\_GEOS\\_Version](#), [PostGIS\\_LibXML\\_Version](#), [PostGIS\\_PROJ\\_Version](#), [PostGIS\\_Version](#)

### 8.3.9 PostGIS\_PROJ\_Version

PostGIS\_PROJ\_Version — Returns the version number of the PROJ4 library.

#### Synopsis

```
text PostGIS_PROJ_Version();
```

#### Description

Returns the version number of the PROJ4 library, or NULL if PROJ4 support is not enabled.

#### Examples

```
SELECT PostGIS_PROJ_Version();
 postgis_proj_version

Rel. 4.4.9, 29 Oct 2004
(1 row)
```

**See Also**

[PostGIS\\_Full\\_Version](#), [PostGIS\\_GEOS\\_Version](#), [PostGIS\\_Lib\\_Version](#), [PostGIS\\_LibXML\\_Version](#), [PostGIS\\_Version](#)

**8.3.10 PostGIS\_Scripts\_Build\_Date**

PostGIS\_Scripts\_Build\_Date — Returns build date of the PostGIS scripts.

**Synopsis**

```
text PostGIS_Scripts_Build_Date();
```

**Description**

Returns build date of the PostGIS scripts.

Availability: 1.0.0RC1

**Examples**

```
SELECT PostGIS_Scripts_Build_Date();
 postgis_scripts_build_date

2007-08-18 09:09:26
(1 row)
```

**See Also**

[PostGIS\\_Full\\_Version](#), [PostGIS\\_GEOS\\_Version](#), [PostGIS\\_Lib\\_Version](#), [PostGIS\\_LibXML\\_Version](#), [PostGIS\\_Version](#)

**8.3.11 PostGIS\_Scripts\_Installed**

PostGIS\_Scripts\_Installed — Returns version of the postgis scripts installed in this database.

**Synopsis**

```
text PostGIS_Scripts_Installed();
```

**Description**

Returns version of the postgis scripts installed in this database.

**Note**

If the output of this function doesn't match the output of [PostGIS\\_Scripts\\_Released](#) you probably missed to properly upgrade an existing database. See the [Upgrading](#) section for more info.

---

Availability: 0.9.0

---

## Examples

```
SELECT PostGIS_Scripts_Installed();
 postgis_scripts_installed

 1.5.0SVN
(1 row)
```

## See Also

[PostGIS\\_Full\\_Version](#), [PostGIS\\_Scripts\\_Released](#), [PostGIS\\_Version](#)

### 8.3.12 PostGIS\_Scripts\_Released

`PostGIS_Scripts_Released` — Returns the version number of the `postgis.sql` script released with the installed `postgis` lib.

#### Synopsis

```
text PostGIS_Scripts_Released();
```

#### Description

Returns the version number of the `postgis.sql` script released with the installed `postgis` lib.

#### Note

Starting with version 1.1.0 this function returns the same value of [PostGIS\\_Lib\\_Version](#). Kept for backward compatibility.

Availability: 0.9.0

## Examples

```
SELECT PostGIS_Scripts_Released();
 postgis_scripts_released

 1.3.4SVN
(1 row)
```

## See Also

[PostGIS\\_Full\\_Version](#), [PostGIS\\_Scripts\\_Installed](#), [PostGIS\\_Lib\\_Version](#)

### 8.3.13 PostGIS\_Version

`PostGIS_Version` — Returns PostGIS version number and compile-time options.

#### Synopsis

```
text PostGIS_Version();
```

---

## Description

Returns PostGIS version number and compile-time options.

## Examples

```
SELECT PostGIS_Version();
 postgis_version

1.3 USE_GEOS=1 USE_PROJ=1 USE_STATS=1
(1 row)
```

## See Also

[PostGIS\\_Full\\_Version](#), [PostGIS\\_GEOS\\_Version](#), [PostGIS\\_Lib\\_Version](#), [PostGIS\\_LibXML\\_Version](#), [PostGIS\\_PROJ\\_Version](#)

### 8.3.14 Populate\_Geometry\_Columns

`Populate_Geometry_Columns` — Ensures geometry columns are defined with type modifiers or have appropriate spatial constraints. This ensures they will be registered correctly in `geometry_columns` view. By default will convert all geometry columns with no type modifier to ones with type modifiers. To get old behavior set `use_typmod=false`

## Synopsis

```
text Populate_Geometry_Columns(boolean use_typmod=true);
int Populate_Geometry_Columns(oid relation_oid, boolean use_typmod=true);
```

## Description

Ensures geometry columns have appropriate type modifiers or spatial constraints to ensure they are registered correctly in `geometry_columns` table.

For backwards compatibility and for spatial needs such as table inheritance where each child table may have different geometry type, the old check constraint behavior is still supported. If you need the old behavior, you need to pass in the new optional argument as false `use_typmod=false`. When this is done geometry columns will be created with no type modifiers but will have 3 constraints defined. In particular, this means that every geometry column belonging to a table has at least three constraints:

- `enforce_dims_the_geom` - ensures every geometry has the same dimension (see [ST\\_NDims](#))
- `enforce_geotype_the_geom` - ensures every geometry is of the same type (see [GeometryType](#))
- `enforce_srid_the_geom` - ensures every geometry is in the same projection (see [ST\\_SRID](#))

If a table `oid` is provided, this function tries to determine the srid, dimension, and geometry type of all geometry columns in the table, adding constraints as necessary. If successful, an appropriate row is inserted into the `geometry_columns` table, otherwise, the exception is caught and an error notice is raised describing the problem.

If the `oid` of a view is provided, as with a table `oid`, this function tries to determine the srid, dimension, and type of all the geometries in the view, inserting appropriate entries into the `geometry_columns` table, but nothing is done to enforce constraints.

The parameterless variant is a simple wrapper for the parameterized variant that first truncates and repopulates the `geometry_columns` table for every spatial table and view in the database, adding spatial constraints to tables where appropriate. It returns a summary of the number of geometry columns detected in the database and the number that were inserted into the `geom`

etry\_columns table. The parameterized version simply returns the number of rows inserted into the geometry\_columns table.

Availability: 1.4.0

Changed: 2.0.0 By default, now uses type modifiers instead of check constraints to constrain geometry types. You can still use check constraint behavior instead by using the new use\_typmod and setting it to false.

Enhanced: 2.0.0 use\_typmod optional argument was introduced that allows controlling if columns are created with typmodifiers or with check constraints.

## Examples

```
CREATE TABLE public.myspatial_table(gid serial, geom geometry);
INSERT INTO myspatial_table(geom) VALUES(ST_GeomFromText('LINESTRING(1 2, 3 4)',4326));
-- This will now use typ modifiers. For this to work, there must exist data
SELECT Populate_Geometry_Columns('public.myspatial_table'::regclass);
```

```
populate_geometry_columns

 1

\d myspatial_table

Table "public.myspatial_table"
Column | Type | Modifiers
-----+-----+-----
gid | integer | not null default nextval('myspatial_table_gid_seq'::<
 regclass)
geom | geometry(LineString,4326) |
```

```
-- This will change the geometry columns to use constraints if they are not typmod or have <
 constraints already.
--For this to work, there must exist data
CREATE TABLE public.myspatial_table_cs(gid serial, geom geometry);
INSERT INTO myspatial_table_cs(geom) VALUES(ST_GeomFromText('LINESTRING(1 2, 3 4)',4326));
SELECT Populate_Geometry_Columns('public.myspatial_table_cs'::regclass, false);
populate_geometry_columns

 1

\d myspatial_table_cs

Table "public.myspatial_table_cs"
Column | Type | Modifiers
-----+-----+-----
gid | integer | not null default nextval('myspatial_table_cs_gid_seq'::regclass)
geom | geometry |
Check constraints:
 "enforce_dims_geom" CHECK (st_ndims(geom) = 2)
 "enforce_geotype_geom" CHECK (geometrytype(geom) = 'LINESTRING'::text OR geom IS NULL)
 "enforce_srid_geom" CHECK (st_srid(geom) = 4326)
```

### 8.3.15 UpdateGeometrySRID

UpdateGeometrySRID — Updates the SRID of all features in a geometry column, geometry\_columns metadata and srid. If it was enforced with constraints, the constraints will be updated with new srid constraint. If the old was enforced by type definition, the type definition will be changed.

## Synopsis

```
text UpdateGeometrySRID(varchar table_name, varchar column_name, integer srid);
text UpdateGeometrySRID(varchar schema_name, varchar table_name, varchar column_name, integer srid);
text UpdateGeometrySRID(varchar catalog_name, varchar schema_name, varchar table_name, varchar column_name, integer srid);
```

## Description

Updates the SRID of all features in a geometry column, updating constraints and reference in geometry\_columns. Note: uses current\_schema() on schema-aware postgres installations if schema is not provided.

This function supports 3d and will not drop the z-index.

This method supports Circular Strings and Curves

## Examples

This will change the srid of the roads table to 4326 from whatever it was before

```
SELECT UpdateGeometrySRID('roads', 'geom', 4326);
```

The prior example is equivalent to this DDL statement

```
ALTER TABLE roads
 ALTER COLUMN geom TYPE geometry(MULTILINESTRING, 4326)
 USING ST_SetSRID(geom, 4326);
```

If you got the projection wrong (or brought it in as unknown) in load and you wanted to transform to web mercator all in one shot You can do this with DDL but there is no equivalent PostGIS management function to do so in one go.

```
ALTER TABLE roads
 ALTER COLUMN geom TYPE geometry(MULTILINESTRING, 3857) USING ST_Transform(ST_SetSRID(geom ←
 , 4326), 3857) ;
```

## See Also

[UpdateRasterSRID](#), [ST\\_SetSRID](#), [ST\\_Transform](#)

## 8.4 Geometry Constructors

### 8.4.1 ST\_BdPolyFromText

**ST\_BdPolyFromText** — Construct a Polygon given an arbitrary collection of closed linestrings as a MultiLineString Well-Known text representation.

## Synopsis

```
geometry ST_BdPolyFromText(text WKT, integer srid);
```

## Description

Construct a Polygon given an arbitrary collection of closed linestrings as a MultiLineString Well-Known text representation.

### Note

Throws an error if WKT is not a MULTILINESTRING. Throws an error if output is a MULTIPOLYGON; use `ST_BdMPolyFromText` in that case, or see `ST_BuildArea()` for a postgres-specific approach.

This method implements the [OpenGIS Simple Features Implementation Specification for SQL 1.1](#). s3.2.6.2

Availability: 1.1.0 - requires GEOS >= 2.1.0.

## Examples

Forthcoming

## See Also

[ST\\_BuildArea](#), [ST\\_BdMPolyFromText](#)

## 8.4.2 ST\_BdMPolyFromText

`ST_BdMPolyFromText` — Construct a MultiPolygon given an arbitrary collection of closed linestrings as a MultiLineString text representation Well-Known text representation.

## Synopsis

```
geometry ST_BdMPolyFromText(text WKT, integer srid);
```

## Description

Construct a Polygon given an arbitrary collection of closed linestrings, polygons, MultiLineStrings as Well-Known text representation.

### Note

Throws an error if WKT is not a MULTILINESTRING. Forces MULTIPOLYGON output even when result is really only composed by a single POLYGON; use [ST\\_BdPolyFromText](#) if you're sure a single POLYGON will result from operation, or see [ST\\_BuildArea\(\)](#) for a postgres-specific approach.

This method implements the [OpenGIS Simple Features Implementation Specification for SQL 1.1](#). s3.2.6.2

Availability: 1.1.0 - requires GEOS >= 2.1.0.

## Examples

Forthcoming

**See Also**

[ST\\_BuildArea](#), [ST\\_BdPolyFromText](#)

**8.4.3 ST\_Box2dFromGeoHash**

`ST_Box2dFromGeoHash` — Return a BOX2D from a GeoHash string.

**Synopsis**

```
box2d ST_Box2dFromGeoHash(text geohash, integer precision=full_precision_of_geohash);
```

**Description**

Return a BOX2D from a GeoHash string.

If no `precision` is specified `ST_Box2dFromGeoHash` returns a BOX2D based on full precision of the input GeoHash string.

If `precision` is specified `ST_Box2dFromGeoHash` will use that many characters from the GeoHash to create the BOX2D. Lower precision values results in larger BOX2Ds and larger values increase the precision.

Availability: 2.1.0

**Examples**

```
SELECT ST_Box2dFromGeoHash('9qqj7nmxcggy4d0dbxqz0');
 st_geomfromgeohash

BOX(-115.172816 36.114646,-115.172816 36.114646)

SELECT ST_Box2dFromGeoHash('9qqj7nmxcggy4d0dbxqz0', 0);
 st_box2dfromgeohash

BOX(-180 -90,180 90)

SELECT ST_Box2dFromGeoHash('9qqj7nmxcggy4d0dbxqz0', 10);
 st_box2dfromgeohash

BOX(-115.17282128334 36.1146408319473,-115.172810554504 36.1146461963654)
```

**See Also**

[ST\\_GeoHash](#), [ST\\_GeomFromGeoHash](#), [ST\\_PointFromGeoHash](#)

**8.4.4 ST\_GeogFromText**

`ST_GeogFromText` — Return a specified geography value from Well-Known Text representation or extended (WKT).

**Synopsis**

```
geography ST_GeogFromText(text EWKT);
```

## Description

Returns a geography object from the well-known text or extended well-known representation. SRID 4326 is assumed if unspecified. This is an alias for `ST_GeographyFromText`. Points are always expressed in long lat form.

## Examples

```
--- converting lon lat coords to geography
ALTER TABLE sometable ADD COLUMN geog geography(POINT,4326);
UPDATE sometable SET geog = ST_GeogFromText('SRID=4326;POINT(' || lon || ' ' || lat || ')') ←
;

--- specify a geography point using EPSG:4267, NAD27
SELECT ST_AsEWKT(ST_GeogFromText('SRID=4267;POINT(-77.0092 38.889588)'));
```

## See Also

[ST\\_AsText](#), [ST\\_GeographyFromText](#)

### 8.4.5 ST\_GeographyFromText

`ST_GeographyFromText` — Return a specified geography value from Well-Known Text representation or extended (WKT).

## Synopsis

```
geography ST_GeographyFromText(text EWKT);
```

## Description

Returns a geography object from the well-known text representation. SRID 4326 is assumed if unspecified.

## See Also

[ST\\_GeogFromText](#), [ST\\_AsText](#)

### 8.4.6 ST\_GeogFromWKB

`ST_GeogFromWKB` — Creates a geography instance from a Well-Known Binary geometry representation (WKB) or extended Well Known Binary (EWKB).

## Synopsis

```
geography ST_GeogFromWKB(bytea wkb);
```

## Description

The `ST_GeogFromWKB` function, takes a well-known binary representation (WKB) of a geometry or PostGIS Extended WKB and creates an instance of the appropriate geography type. This function plays the role of the Geometry Factory in SQL.

If SRID is not specified, it defaults to 4326 (WGS 84 long lat).

This method supports Circular Strings and Curves

## Examples

```
--Although bytea rep contains single \, these need to be escaped when inserting into a table
SELECT ST_AsText(
ST_GeogFromWKB(E'\001\002\000\000\000\000\002\000\000\000\037\205\353Q
\270~\300\323Mb\020X\231C@\020X9\264\310~\300)\217\302\365\230
C@')
);
 st_astext

LINESTRING(-113.98 39.198,-113.981 39.195)
(1 row)
```

## See Also

[ST\\_GeogFromText](#), [ST\\_AsBinary](#)

## 8.4.7 ST\_GeomFromTWKB

**ST\_GeomFromTWKB** — Creates a geometry instance from a TWKB ("Tiny Well-Known Binary") geometry representation.

### Synopsis

geometry **ST\_GeomFromTWKB**(bytea twkb);

### Description

The **ST\_GeomFromTWKB** function, takes a TWKB ("Tiny Well-Known Binary") geometry representation (WKB) and creates an instance of the appropriate geometry type.

## Examples

```
SELECT ST_AsText(ST_GeomFromTWKB(ST_AsTWKB('LINESTRING(126 34, 127 35)::geometry')));
 st_astext

LINESTRING(126 34, 127 35)
(1 row)

SELECT ST_AsEWKT(
 ST_GeomFromTWKB(E'\x620002f7f40dbce4040105')
);
 st_asewkt

LINESTRING(-113.98 39.198,-113.981 39.195)
(1 row)
```

## See Also

[ST\\_AsTWKB](#)

## 8.4.8 ST\_GeomCollFromText

`ST_GeomCollFromText` — Makes a collection Geometry from collection WKT with the given SRID. If SRID is not give, it defaults to 0.

### Synopsis

```
geometry ST_GeomCollFromText(text WKT, integer srid);
geometry ST_GeomCollFromText(text WKT);
```

### Description

Makes a collection Geometry from the Well-Known-Text (WKT) representation with the given SRID. If SRID is not give, it defaults to 0.

OGC SPEC 3.2.6.2 - option SRID is from the conformance suite

Returns null if the WKT is not a GEOMETRYCOLLECTION

#### Note

If you are absolutely sure all your WKT geometries are collections, don't use this function. It is slower than `ST_GeomFromText` since it adds an additional validation step.

This method implements the [OpenGIS Simple Features Implementation Specification for SQL 1.1](#). s3.2.6.2

This method implements the SQL/MM specification.

### Examples

```
SELECT ST_GeomCollFromText('GEOMETRYCOLLECTION(POINT(1 2),LINESTRING(1 2, 3 4))');
```

### See Also

[ST\\_GeomFromText](#), [ST\\_SRID](#)

## 8.4.9 ST\_GeomFromEWKB

`ST_GeomFromEWKB` — Return a specified `ST_Geometry` value from Extended Well-Known Binary representation (EWKB).

### Synopsis

```
geometry ST_GeomFromEWKB(bytea EWKB);
```

## Description

Constructs a PostGIS ST\_Geometry object from the OGC Extended Well-Known binary (EWKT) representation.

### Note

The EWKB format is not an OGC standard, but a PostGIS specific format that includes the spatial reference system (SRID) identifier

Enhanced: 2.0.0 support for Polyhedral surfaces and TIN was introduced.

This function supports 3d and will not drop the z-index.

This method supports Circular Strings and Curves

This function supports Polyhedral surfaces.

This function supports Triangles and Triangulated Irregular Network Surfaces (TIN).

## Examples

line string binary rep of LINESTRING(-71.160281 42.258729,-71.160837 42.259113,-71.161144 42.25932) in NAD 83 long lat (4269).

### Note

NOTE: Even though byte arrays are delimited with \ and may have ', we need to escape both out with \ and " if standard\_conforming\_strings is off. So it does not look exactly like its AsEWKB representation.

```
SELECT ST_GeomFromEWKB(E'\001\002\000\000 \255\020\000\000\003\000\000\000\344 ←
J=
\013B\312Q\300n\303(\010\036!E@'\277E'K
\312Q\300\366{b\235*!E@\225|\354.P\312Q
\300p\231\323e1!E@');
```

### Note

In PostgreSQL 9.1+ - standard\_conforming\_strings is set to on by default, where as in past versions it was set to off. You can change defaults as needed for a single query or at the database or server level. Below is how you would do it with standard\_conforming\_strings = on. In this case we escape the ' with standard ansi ', but slashes are not escaped

```
set standard_conforming_strings = on;
SELECT ST_GeomFromEWKB('\001\002\000\000 \255\020\000\000\003\000\000\000\344J=\012\013B
\312Q\300n\303(\010\036!E@'\277E'K\012\312Q\300\366{b\235*!E@\225|\354.P\312Q\012\300 ←
p\231\323e1')
```

## See Also

## 8.4.10 ST\_GeomFromEWKT

ST\_GeomFromEWKT — Return a specified ST\_Geometry value from Extended Well-Known Text representation (EWKT).

### Synopsis

geometry ST\_GeomFromEWKT(text EWKT);

### Description

Constructs a PostGIS ST\_Geometry object from the OGC Extended Well-Known text (EWKT) representation.

#### Note

The EWKT format is not an OGC standard, but an PostGIS specific format that includes the spatial reference system (SRID) identifier

Enhanced: 2.0.0 support for Polyhedral surfaces and TIN was introduced.

This function supports 3d and will not drop the z-index.

This method supports Circular Strings and Curves

This function supports Polyhedral surfaces.

This function supports Triangles and Triangulated Irregular Network Surfaces (TIN).

### Examples

```
SELECT ST_GeomFromEWKT('SRID=4269;LINESTRING(-71.160281 42.258729,-71.160837 42.259113,-71.161144 42.25932)');
SELECT ST_GeomFromEWKT('SRID=4269;MULTILINESTRING((-71.160281 42.258729,-71.160837 42.259113,-71.161144 42.25932))');

SELECT ST_GeomFromEWKT('SRID=4269;POINT(-71.064544 42.28787)');

SELECT ST_GeomFromEWKT('SRID=4269;POLYGON((-71.1776585052917 42.3902909739571,-71.1776820268866 42.3903701743239,-71.1776063012595 42.3903825660754,-71.1775826583081 42.3903033653531,-71.1776585052917 42.3902909739571))');

SELECT ST_GeomFromEWKT('SRID=4269;MULTIPOLYGON(((-71.1031880899493 42.3152774590236,

### 8.4.11 ST\_GeometryFromText

`ST_GeometryFromText` — Return a specified `ST_Geometry` value from Well-Known Text representation (WKT). This is an alias name for `ST_GeomFromText`

#### Synopsis

```
geometry ST_GeometryFromText(text WKT);
geometry ST_GeometryFromText(text WKT, integer srid);
```

#### Description

This method implements the [OpenGIS Simple Features Implementation Specification for SQL 1.1](#).

This method implements the SQL/MM specification. SQL-MM 3: 5.1.40

[ST\\_GeomFromText](#)

### 8.4.12 ST\_GeomFromGeoHash

`ST_GeomFromGeoHash` — Return a geometry from a GeoHash string.

**Synopsis**

geometry **ST\_GeomFromGeoHash**(text geohash, integer precision=full\_precision\_of\_geohash);

**Description**

Return a geometry from a GeoHash string. The geometry will be a polygon representing the GeoHash bounds.

If no `precision` is specified `ST_GeomFromGeoHash` returns a polygon based on full precision of the input GeoHash string.

If `precision` is specified `ST_GeomFromGeoHash` will use that many characters from the GeoHash to create the polygon.

Availability: 2.1.0

**Examples**

```
SELECT ST_AsText(ST_GeomFromGeoHash('9qqj7nmxnccgyy4d0dbxqz0'));
 st_astext

POLYGON((-115.172816 36.114646,-115.172816 36.114646,-115.172816 36.114646,-115.172816 ←
 36.114646,-115.172816 36.114646))

SELECT ST_AsText(ST_GeomFromGeoHash('9qqj7nmxnccgyy4d0dbxqz0', 4));
 st_astext

POLYGON((-115.3125 36.03515625,-115.3125 36.2109375,-114.9609375 36.2109375,-114.9609375 ←
 36.03515625,-115.3125 36.03515625))

SELECT ST_AsText(ST_GeomFromGeoHash('9qqj7nmxnccgyy4d0dbxqz0', 10));
 st_astext

POLYGON((-115.17282128334 36.1146408319473,-115.17282128334 ←
 36.1146461963654,-115.172810554504 36.1146461963654,-115.172810554504 ←
 36.1146408319473,-115.17282128334 36.1146408319473))
```

**8.4.13 ST\_GeomFromGML**

`ST_GeomFromGML` — Takes as input GML representation of geometry and outputs a PostGIS geometry object

**Synopsis**

geometry **ST\_GeomFromGML**(text geomgml);

geometry **ST\_GeomFromGML**(text geomgml, integer srid);

## Description

Constructs a PostGIS ST\_Geometry object from the OGC GML representation.

ST\_GeomFromGML works only for GML Geometry fragments. It throws an error if you try to use it on a whole GML document.

OGC GML versions supported:

- GML 3.2.1 Namespace
- GML 3.1.1 Simple Features profile SF-2 (with GML 3.1.0 and 3.0.0 backward compatibility)
- GML 2.1.2

OGC GML standards, cf: <http://www.opengeospatial.org/standards/gml>:

Availability: 1.5, requires libxml2 1.6+

Enhanced: 2.0.0 support for Polyhedral surfaces and TIN was introduced.

Enhanced: 2.0.0 default srid optional parameter added.

This function supports 3d and will not drop the z-index.

This function supports Polyhedral surfaces.

This function supports Triangles and Triangulated Irregular Network Surfaces (TIN).

GML allow mixed dimensions (2D and 3D inside the same MultiGeometry for instance). As PostGIS geometries don't, ST\_GeomFromGML convert the whole geometry to 2D if a missing Z dimension is found once.

GML support mixed SRS inside the same MultiGeometry. As PostGIS geometries don't, ST\_GeomFromGML, in this case, reproject all subgeometries to the SRS root node. If no srsName attribute available for the GML root node, the function throw an error.

ST\_GeomFromGML function is not pedantic about an explicit GML namespace. You could avoid to mention it explicitly for common usages. But you need it if you want to use XLink feature inside GML.

### Note

ST\_GeomFromGML function not support SQL/MM curves geometries.

## Examples - A single geometry with srsName

```
SELECT ST_GeomFromGML ('
 <gml:LineString srsName="EPSG:4269">
 <gml:coordinates>
 -71.16028,42.258729 -71.160837,42.259112 -71.161143,42.25932
 </gml:coordinates>
 </gml:LineString>');
```

## Examples - XLink usage

```
SELECT ST_GeomFromGML('
 <gml:LineString xmlns:gml="http://www.opengis.net/gml"
 xmlns:xlink="http://www.w3.org/1999/xlink"
 srsName="urn:ogc:def:crs:EPSG::4269">
 <gml:pointProperty>
 <gml:Point gml:id="p1"><gml:pos>42.258729 -71.16028</gml:pos></gml:Point>
 </gml:pointProperty>
 <gml:pos>42.259112 -71.160837</gml:pos>
 <gml:pointProperty>
 <gml:Point xlink:type="simple" xlink:href="#p1"/>
 </gml:pointProperty>
 </gml:LineString>'););
```

### Examples - Polyhedral Surface

```
SELECT ST_AsEWKT(ST_GeomFromGML('
<gml:PolyhedralSurface>
<gml:polygonPatches>
 <gml:PolygonPatch>
 <gml:exterior>
 <gml:LinearRing><gml:posList srsDimension="3">0 0 0 0 1 0 1 1 0 1 0 0 0 0</gml:posList <←
 </gml:LinearRing>
 </gml:exterior>
 </gml:PolygonPatch>
 <gml:PolygonPatch>
 <gml:exterior>
 <gml:LinearRing><gml:posList srsDimension="3">0 0 0 0 1 0 1 1 0 1 0 0 0 0</gml:posList <←

## 8.4.14 ST\_GeomFromGeoJSON

ST\_GeomFromGeoJSON — Takes as input a geojson representation of a geometry and outputs a PostGIS geometry object

### Synopsis

```
geometry ST_GeomFromGeoJSON(text geomjson);
```

### Description

Constructs a PostGIS geometry object from the GeoJSON representation.

ST\_GeomFromGeoJSON works only for JSON Geometry fragments. It throws an error if you try to use it on a whole JSON document.

Availability: 2.0.0 requires - JSON-C >= 0.9

#### Note

If you do not have JSON-C enabled, support you will get an error notice instead of seeing an output. To enable JSON-C, run configure --with-jsondir=/path/to/json-c. See Section [2.4.1](#) for details.

This function supports 3d and will not drop the z-index.

### Examples

```
SELECT ST_AsText(ST_GeomFromGeoJSON('{"type":"Point","coordinates":[-48.23456,20.12345]}')) ←
 As wkt;
wkt

POINT(-48.23456 20.12345)
```

```
-- a 3D linestring
SELECT ST_AsText(ST_GeomFromGeoJSON('{"type":"LineString","coordinates ←
 ":[[1,2,3], [4,5,6], [7,8,9]]}')) As wkt;
wkt

LINESTRING(1 2,4 5,7 8)
```

**8.4.15 ST\_GeomFromKML**

`ST_GeomFromKML` — Takes as input KML representation of geometry and outputs a PostGIS geometry object

**Synopsis**

```
geometry ST_GeomFromKML(text geomkml);
```

**Description**

Constructs a PostGIS `ST_Geometry` object from the OGC KML representation.

`ST_GeomFromKML` works only for KML Geometry fragments. It throws an error if you try to use it on a whole KML document.

OGC KML versions supported:

- KML 2.2.0 Namespace

OGC KML standards, cf: <http://www.opengeospatial.org/standards/kml>:

Availability: 1.5, libxml2 2.6+

This function supports 3d and will not drop the z-index.

**Note**

`ST_GeomFromKML` function not support SQL/MM curves geometries.

**Examples - A single geometry with srsName**

```
SELECT ST_GeomFromKML ('
 <LineString>
 <coordinates>-71.1663,42.2614
 -71.1667,42.2616</coordinates>
 </LineString>');
```

**See Also**

[Section 2.4.1](#), [ST\\_AsKML](#)

**8.4.16 ST\_GMLToSQL**

`ST_GMLToSQL` — Return a specified `ST_Geometry` value from GML representation. This is an alias name for `ST_GeomFromGML`

**Synopsis**

```
geometry ST_GMLToSQL(text geomgml);
geometry ST_GMLToSQL(text geomgml, integer srid);
```

## Description

This method implements the SQL/MM specification. SQL-MM 3: 5.1.50 (except for curves support).

Availability: 1.5, requires libxml2 1.6+

Enhanced: 2.0.0 support for Polyhedral surfaces and TIN was introduced.

Enhanced: 2.0.0 default srid optional parameter added.

## See Also

Section [2.4.1](#), [ST\\_GeomFromGML](#), [ST\\_AsGML](#)

## 8.4.17 ST\_GeomFromText

ST\_GeomFromText — Return a specified ST\_Geometry value from Well-Known Text representation (WKT).

## Synopsis

```
geometry ST_GeomFromText(text WKT);
geometry ST_GeomFromText(text WKT, integer srid);
```

## Description

Constructs a PostGIS ST\_Geometry object from the OGC Well-Known text representation.

### Note

There are two variants of ST\_GeomFromText function. The first takes no SRID and returns a geometry with no defined spatial reference system (SRID=0). The second takes a SRID as the second argument and returns a geometry that includes this SRID as part of its metadata.

This method implements the [OpenGIS Simple Features Implementation Specification for SQL 1.1](#). s3.2.6.2 - option SRID is from the conformance suite.

This method implements the SQL/MM specification. SQL-MM 3: 5.1.40

This method supports Circular Strings and Curves

### Warning

Changed: 2.0.0 In prior versions of PostGIS ST\_GeomFromText('GEOMETRYCOLLECTION(EMPTY)') was allowed. This is now illegal in PostGIS 2.0.0 to better conform with SQL/MM standards. This should now be written as ST\_GeomFromText('GEOMETRYCOLLECTION EMPTY')

## Examples

```

SELECT ST_GeomFromText('LINESTRING(-71.160281 42.258729,-71.160837 42.259113,-71.161144 42.25932)');
SELECT ST_GeomFromText('LINESTRING(-71.160281 42.258729,-71.160837 42.259113,-71.161144 42.25932)',4269);

SELECT ST_GeomFromText('MULTILINESTRING((-71.160281 42.258729,-71.160837 42.259113,-71.161144 42.25932))');

### 8.4.18 ST\_GeomFromWKB

**ST\_GeomFromWKB** — Creates a geometry instance from a Well-Known Binary geometry representation (WKB) and optional SRID.

#### Synopsis

```

geometry ST_GeomFromWKB(bytea geom);
geometry ST_GeomFromWKB(bytea geom, integer srid);

```

## Description

The `ST_GeomFromWKB` function, takes a well-known binary representation of a geometry and a Spatial Reference System ID (SRID) and creates an instance of the appropriate geometry type. This function plays the role of the Geometry Factory in SQL. This is an alternate name for `ST_WKBToSQL`.

If SRID is not specified, it defaults to 0 (Unknown).

This method implements the [OpenGIS Simple Features Implementation Specification for SQL 1.1](#), s3.2.7.2 - the optional SRID is from the conformance suite

This method implements the SQL/MM specification. SQL-MM 3: 5.1.41

This method supports Circular Strings and Curves

## Examples

```
--Although bytea rep contains single \, these need to be escaped when inserting into a table
-- unless standard_conforming_strings is set to on.
SELECT ST_AsEWKT(
ST_GeomFromWKB(E'\001\002\000\000\000\002\000\000\000\0037\205\353Q
\270~\300\323Mb\020X\231C@020X9\264\310~\300)\217\302\365\230
C@',4326)
);
 st_asewkt

SRID=4326;LINESTRING(-113.98 39.198,-113.981 39.195)
(1 row)

SELECT
 ST_AsText (
 ST_GeomFromWKB (
 ST_AsEWKB ('POINT(2 5) '::geometry)
)
);
 st_astext

POINT(2 5)
(1 row)
```

### 8.4.19 ST\_LineFromEncodedPolyline

`ST_LineFromEncodedPolyline` — Creates a LineString from an Encoded Polyline.

#### Synopsis

geometry `ST_LineFromEncodedPolyline`(text polyline, integer precision=5);

## Description

Creates a LineString from an Encoded Polyline string.

See <http://developers.google.com/maps/documentation/utilities/polylinealgorithm>

Availability: 2.2.0

## Examples

```
--Create a line string from a polyline
SELECT ST_AsEWKT(ST_LineFromEncodedPolyline('p~iF~ps|U_ulLnnqC_mqNvxq`@'));
--result--
LINESTRING(-120.2 38.5,-120.95 40.7,-126.453 43.252)
```

## See Also

[ST\\_AsEncodedPolyline](#)

## 8.4.20 ST\_LineFromMultiPoint

`ST_LineFromMultiPoint` — Creates a LineString from a MultiPoint geometry.

### Synopsis

```
geometry ST_LineFromMultiPoint(geometry aMultiPoint);
```

### Description

Creates a LineString from a MultiPoint geometry.

This function supports 3d and will not drop the z-index.

## Examples

```
--Create a 3d line string from a 3d multipoint
SELECT ST_AsEWKT(ST_LineFromMultiPoint(ST_GeomFromEWKT('MULTIPOINT(1 2 3, 4 5 6, 7 8 9)'))) ←
;
--result--
LINESTRING(1 2 3,4 5 6,7 8 9)
```

## See Also

[ST\\_AsEWKT](#), [ST\\_Collect](#), [ST\\_MakeLine](#)

## 8.4.21 ST\_LineFromText

`ST_LineFromText` — Makes a Geometry from WKT representation with the given SRID. If SRID is not given, it defaults to 0.

## Synopsis

geometry **ST\_LineFromText**(text WKT);  
 geometry **ST\_LineFromText**(text WKT, integer srid);

## Description

Makes a Geometry from WKT with the given SRID. If SRID is not give, it defaults to 0. If WKT passed in is not a LINESTRING, then null is returned.

### Note

OGC SPEC 3.2.6.2 - option SRID is from the conformance suite.

### Note

If you know all your geometries are LINESTRINGS, its more efficient to just use ST\_GeomFromText. This just calls ST\_GeomFromText and adds additional validation that it returns a linestring.

This method implements the [OpenGIS Simple Features Implementation Specification for SQL 1.1](#). s3.2.6.2

This method implements the SQL/MM specification. SQL-MM 3: 7.2.8

## Examples

```
SELECT ST_LineFromText('LINESTRING(1 2, 3 4)') AS aline, ST_LineFromText('POINT(1 2)') AS ↵
 null_return;
aline | null_return

01020000000020000000000000000000F ... | t
```

## See Also

## 8.4.22 ST\_LineFromWKB

**ST\_LineFromWKB** — Makes a LINESTRING from WKB with the given SRID

## Synopsis

geometry **ST\_LineFromWKB**(bytea WKB);  
 geometry **ST\_LineFromWKB**(bytea WKB, integer srid);

## Description

The `ST_LineFromWKB` function, takes a well-known binary representation of geometry and a Spatial Reference System ID (SRID) and creates an instance of the appropriate geometry type - in this case, a `LINestring` geometry. This function plays the role of the Geometry Factory in SQL.

If an SRID is not specified, it defaults to 0. `NULL` is returned if the input `bytea` does not represent a `LINestring`.

### Note

OGC SPEC 3.2.6.2 - option SRID is from the conformance suite.

### Note

If you know all your geometries are `LINestring`s, its more efficient to just use `ST_GeomFromWKB`. This function just calls `ST_GeomFromWKB` and adds additional validation that it returns a `linestring`.

This method implements the [OpenGIS Simple Features Implementation Specification for SQL 1.1](#). s3.2.6.2

This method implements the SQL/MM specification. SQL-MM 3: 7.2.9

## Examples

```
SELECT ST_LineFromWKB(ST_AsBinary(ST_GeomFromText('LINestring(1 2, 3 4)'))) AS aline,
 ST_LineFromWKB(ST_AsBinary(ST_GeomFromText('POINT(1 2)'))) IS NULL AS null_return;
aline	null_return
01020000000200000000000000000000F ... | t
```

## See Also

[ST\\_GeomFromWKB](#), [ST\\_LinestringFromWKB](#)

### 8.4.23 ST\_LinestringFromWKB

`ST_LinestringFromWKB` — Makes a geometry from WKB with the given SRID.

## Synopsis

```
geometry ST_LinestringFromWKB(bytea WKB);
geometry ST_LinestringFromWKB(bytea WKB, integer srid);
```

## Description

The `ST_LinestringFromWKB` function, takes a well-known binary representation of geometry and a Spatial Reference System ID (SRID) and creates an instance of the appropriate geometry type - in this case, a `LINestring` geometry. This function plays the role of the Geometry Factory in SQL.

If an SRID is not specified, it defaults to 0. `NULL` is returned if the input `bytea` does not represent a `LINestring` geometry. This an alias for [ST\\_LineFromWKB](#).

**Note**

OGC SPEC 3.2.6.2 - optional SRID is from the conformance suite.

**Note**

If you know all your geometries are `LINESTRINGS`, it's more efficient to just use `ST_GeomFromWKB`. This function just calls `ST_GeomFromWKB` and adds additional validation that it returns a `LINESTRING`.

This method implements the [OpenGIS Simple Features Implementation Specification for SQL 1.1](#). s3.2.6.2

This method implements the SQL/MM specification. SQL-MM 3: 7.2.9

**Examples**

```
SELECT
 ST_LineStringFromWKB (
 ST_AsBinary (ST_GeomFromText ('LINESTRING(1 2, 3 4)'))
) AS aline,
 ST_LineStringFromWKB (
 ST_AsBinary (ST_GeomFromText ('POINT(1 2)'))
) IS NULL AS null_return;
aline	null_return
01020000000200000000000000000000F ... | t
```

**See Also**

**8.4.24 ST\_MakeBox2D**

`ST_MakeBox2D` — Creates a BOX2D defined by the given point geometries.

**Synopsis**

```
box2d ST_MakeBox2D(geometry pointLowLeft, geometry pointUpRight);
```

**Description**

Creates a BOX2D defined by the given point geometries. This is useful for doing range queries

**Examples**

```
--Return all features that fall reside or partly reside in a US national atlas coordinate ←
 bounding box
--It is assumed here that the geometries are stored with SRID = 2163 (US National atlas ←
 equal area)
SELECT feature_id, feature_name, the_geom
```

```
FROM features
WHERE the_geom && ST_SetSRID(ST_MakeBox2D(ST_Point(-989502.1875, 528439.5625),
 ST_Point(-987121.375 , 529933.1875)), 2163)
```

### See Also

## 8.4.25 ST\_3DMakeBox

ST\_3DMakeBox — Creates a BOX3D defined by the given 3d point geometries.

### Synopsis

```
box3d ST_3DMakeBox(geometry point3DLowLeftBottom, geometry point3DUpRightTop);
```

### Description

Creates a BOX3D defined by the given 2 3D point geometries.

This function supports 3d and will not drop the z-index.

Changed: 2.0.0 In prior versions this used to be called ST\_MakeBox3D

### Examples

```
SELECT ST_3DMakeBox(ST_MakePoint(-989502.1875, 528439.5625, 10),
 ST_MakePoint(-987121.375 , 529933.1875, 10)) As abb3d
```

```
--bb3d--

```

```
BOX3D(-989502.1875 528439.5625 10,-987121.375 529933.1875 10)
```

### See Also

[ST\\_MakePoint](#), [ST\\_SetSRID](#), [ST\\_SRID](#)

## 8.4.26 ST\_MakeLine

ST\_MakeLine — Creates a Linestring from point, multipoint, or line geometries.

### Synopsis

```
geometry ST_MakeLine(geometry set geoms);
geometry ST_MakeLine(geometry geom1, geometry geom2);
geometry ST_MakeLine(geometry[] geoms_array);
```

## Description

`ST_MakeLine` comes in 3 forms: a spatial aggregate that takes rows of point, multipoint, or line geometries and returns a line string, a function that takes an array of point, multipoint, or line, and a regular function that takes two point, multipoint, or line geometries. You might want to use a subselect to order points before feeding them to the aggregate version of this function.

Inputs other than point, multipoint, or lines are ignored.

When adding line components common nodes at the beginning of lines are removed from the output. Common nodes in point and multipoint inputs are not removed.

This function supports 3d and will not drop the z-index.

Availability: 2.3.0 - Support for multipoint input elements was introduced

Availability: 2.0.0 - Support for linestring input elements was introduced

Availability: 1.4.0 - `ST_MakeLine(geomarray)` was introduced. `ST_MakeLine` aggregate functions was enhanced to handle more points faster.

## Examples: Spatial Aggregate version

This example takes a sequence of GPS points and creates one record for each gps travel where the geometry field is a line string composed of the gps points in the order of the travel.

```
-- For pre-PostgreSQL 9.0 - this usually works,
-- but the planner may on occasion choose not to respect the order of the subquery
SELECT gps.gps_track, ST_MakeLine(gps.the_geom) As newgeom
FROM (SELECT gps_track, gps_time, the_geom
 FROM gps_points ORDER BY gps_track, gps_time) As gps
GROUP BY gps.gps_track;
```

```
-- If you are using PostgreSQL 9.0+
-- (you can use the new ORDER BY support for aggregates)
-- this is a guaranteed way to get a correctly ordered linestring
-- Your order by part can order by more than one column if needed
SELECT gps.gps_track, ST_MakeLine(gps.the_geom ORDER BY gps_time) As newgeom
FROM gps_points As gps
GROUP BY gps.gps_track;
```

## Examples: Non-Spatial Aggregate version

First example is a simple one off line string composed of 2 points. The second formulates line strings from 2 points a user draws. The third is a one-off that joins 2 3d points to create a line in 3d space.

```
SELECT ST_AsText (ST_MakeLine (ST_MakePoint (1,2), ST_MakePoint (3,4)));
 st_astext

LINESTRING(1 2,3 4)

SELECT userpoints.id, ST_MakeLine(startpoint, endpoint) As drawn_line
FROM userpoints ;

SELECT ST_AsEWKT (ST_MakeLine (ST_MakePoint (1,2,3), ST_MakePoint (3,4,5)));
 st_asewkt

LINESTRING(1 2 3,3 4 5)
```

**Examples: Using Array version**

```
SELECT ST_MakeLine (ARRAY (SELECT ST_Centroid(the_geom) FROM visit_locations ORDER BY visit_time));

--Making a 3d line with 3 3-d points
SELECT ST_AsEWKT(ST_MakeLine (ARRAY [ST_MakePoint (1,2,3),
 ST_MakePoint (3,4,5), ST_MakePoint (6,6,6)]));
 st_asewkt

LINESTRING(1 2 3,3 4 5,6 6 6)
```

**See Also**

[ST\\_AsEWKT](#), [ST\\_AsText](#), [ST\\_GeomFromText](#), [ST\\_MakePoint](#)

**8.4.27 ST\_MakeEnvelope**

**ST\_MakeEnvelope** — Creates a rectangular Polygon formed from the given minimums and maximums. Input values must be in SRS specified by the SRID.

**Synopsis**

geometry **ST\_MakeEnvelope**(double precision xmin, double precision ymin, double precision xmax, double precision ymax, integer srid=unknown);

**Description**

Creates a rectangular Polygon formed from the minima and maxima. by the given shell. Input values must be in SRS specified by the SRID. If no SRID is specified the unknown spatial reference system is assumed

Availability: 1.5

Enhanced: 2.0: Ability to specify an envelope without specifying an SRID was introduced.

**Example: Building a bounding box polygon**

```
SELECT ST_AsText (ST_MakeEnvelope (10, 10, 11, 11, 4326));

st_asewkt

POLYGON((10 10, 10 11, 11 11, 11 10, 10 10))
```

**See Also**

[ST\\_MakePoint](#), [ST\\_MakeLine](#), [ST\\_MakePolygon](#)

**8.4.28 ST\_MakePolygon**

**ST\_MakePolygon** — Creates a Polygon formed by the given shell. Input geometries must be closed LINESTRINGS.

## Synopsis

geometry **ST\_MakePolygon**(geometry linestring);

geometry **ST\_MakePolygon**(geometry outerlinestring, geometry[] interiorlinestrings);

## Description

Creates a Polygon formed by the given shell. Input geometries must be closed **LINESTRINGS**. Comes in 2 variants.

Variant 1: Takes one closed linestring.

Variant 2: Creates a Polygon formed by the given shell and array of holes. You can construct a geometry array using **ST\_Accum** or the PostgreSQL **ARRAY[]** and **ARRAY()** constructs. Input geometries must be closed **LINESTRINGS**.

### Note

This function will not accept a **MULTILINESTRING**. Use **ST\_LineMerge** or **ST\_Dump** to generate line strings.

This function supports 3d and will not drop the z-index.

## Examples: Single closed **LINESTRING**

```
--2d line
SELECT ST_MakePolygon(ST_GeomFromText('LINESTRING(75.15 29.53,77 29,77.6 29.5, 75.15 29.53) ←
 '));
--If linestring is not closed
--you can add the start point to close it
SELECT ST_MakePolygon(ST_AddPoint(foo.open_line, ST_StartPoint(foo.open_line)))
FROM (
SELECT ST_GeomFromText('LINESTRING(75.15 29.53,77 29,77.6 29.5)') As open_line) As foo;

--3d closed line
SELECT ST_MakePolygon(ST_GeomFromText('LINESTRING(75.15 29.53 1,77 29 1,77.6 29.5 1, 75.15 ←
 29.53 1)'));

st_asewkt

POLYGON((75.15 29.53 1,77 29 1,77.6 29.5 1,75.15 29.53 1))

--measured line --
SELECT ST_MakePolygon(ST_GeomFromText('LINESTRINGM(75.15 29.53 1,77 29 1,77.6 29.5 2, 75.15 ←
 29.53 2)'));

st_asewkt

POLYGONM((75.15 29.53 1,77 29 1,77.6 29.5 2,75.15 29.53 2))
```

## Examples: Outer shell with inner shells

### Build a donut with an ant hole

```
SELECT ST_MakePolygon(
 ST_ExteriorRing(ST_Buffer(foo.line,10)),
 ARRAY[ST_Translate(foo.line,1,1),
 ST_ExteriorRing(ST_Buffer(ST_MakePoint(20,20),1))]
```

```

)
FROM
 (SELECT ST_ExteriorRing(ST_Buffer(ST_MakePoint(10,10),10,10))
 As line)
 As foo;

```

Build province boundaries with holes representing lakes in the province from a set of province polygons/multipolygons and water linestrings. This is an example of using PostGIS `ST_Accum`.

**Note**

The CASE construct is used because feeding a null array into `ST_MakePolygon` results in NULL.

**Note**

A left join is used to guarantee we get all provinces back even if they have no lakes.

```

SELECT p.gid, p.province_name,
 CASE WHEN
 ST_Accum(w.the_geom) IS NULL THEN p.the_geom
 ELSE ST_MakePolygon(ST_LineMerge(ST_Boundary(p.the_geom)), ST_Accum(w.the_geom)) END
FROM
 provinces p LEFT JOIN waterlines w
 ON (ST_Within(w.the_geom, p.the_geom) AND ST_IsClosed(w.the_geom))
GROUP BY p.gid, p.province_name, p.the_geom;

--Same example above but utilizing a correlated subquery
--and PostgreSQL built-in ARRAY() function that converts a row set to an array

SELECT p.gid, p.province_name, CASE WHEN
 EXISTS(SELECT w.the_geom
 FROM waterlines w
 WHERE ST_Within(w.the_geom, p.the_geom)
 AND ST_IsClosed(w.the_geom))
 THEN
 ST_MakePolygon(ST_LineMerge(ST_Boundary(p.the_geom)),
 ARRAY(SELECT w.the_geom
 FROM waterlines w
 WHERE ST_Within(w.the_geom, p.the_geom)
 AND ST_IsClosed(w.the_geom)))
 ELSE p.the_geom END As the_geom
FROM
 provinces p;

```

**See Also**

**8.4.29 ST\_MakePoint**

`ST_MakePoint` — Creates a 2D,3DZ or 4D point geometry.

## Synopsis

geometry **ST\_MakePoint**(double precision x, double precision y);

geometry **ST\_MakePoint**(double precision x, double precision y, double precision z);

geometry **ST\_MakePoint**(double precision x, double precision y, double precision z, double precision m);

## Description

Creates a 2D,3DZ or 4D point geometry (geometry with measure). `ST_MakePoint` while not being OGC compliant is generally faster and more precise than `ST_GeomFromText` and `ST_PointFromText`. It is also easier to use if you have raw coordinates rather than WKT.

**Note**

Note x is longitude and y is latitude

**Note**

Use `ST_MakePointM` if you need to make a point with x,y,m.

This function supports 3d and will not drop the z-index.

## Examples

```
--Return point with unknown SRID
SELECT ST_MakePoint(-71.1043443253471, 42.3150676015829);

--Return point marked as WGS 84 long lat
SELECT ST_SetSRID(ST_MakePoint(-71.1043443253471, 42.3150676015829), 4326);

--Return a 3D point (e.g. has altitude)
SELECT ST_MakePoint(1, 2, 1.5);

--Get z of point
SELECT ST_Z(ST_MakePoint(1, 2, 1.5));
result

1.5
```

## See Also

### 8.4.30 ST\_MakePointM

`ST_MakePointM` — Creates a point geometry with an x y and m coordinate.

## Synopsis

geometry **ST\_MakePointM**(float x, float y, float m);

**Description**

Creates a point with x, y and measure coordinates.

**Note**

Note x is longitude and y is latitude.

**Examples**

We use `ST_AsEWKT` in these examples to show the text representation instead of `ST_AsText` because `ST_AsText` does not support returning M.

```
--Return EWKT representation of point with unknown SRID
SELECT ST_AsEWKT(ST_MakePointM(-71.1043443253471, 42.3150676015829, 10));

--result
 st_asewkt

POINTM(-71.1043443253471 42.3150676015829 10)

--Return EWKT representation of point with measure marked as WGS 84 long lat
SELECT ST_AsEWKT(ST_SetSRID(ST_MakePointM(-71.1043443253471, 42.3150676015829,10),4326));

 st_asewkt

SRID=4326;POINTM(-71.1043443253471 42.3150676015829 10)

--Return a 3d point (e.g. has altitude)
SELECT ST_MakePoint(1, 2,1.5);

--Get m of point
SELECT ST_M(ST_MakePointM(-71.1043443253471, 42.3150676015829,10));
result

10
```

**See Also**

[ST\\_AsEWKT](#), [ST\\_MakePoint](#), [ST\\_SetSRID](#)

**8.4.31 ST\_MLineFromText**

`ST_MLineFromText` — Return a specified `ST_MultiLineString` value from WKT representation.

**Synopsis**

```
geometry ST_MLineFromText(text WKT, integer srid);
geometry ST_MLineFromText(text WKT);
```

**Description**

Makes a Geometry from Well-Known-Text (WKT) with the given SRID. If SRID is not give, it defaults to 0.

OGC SPEC 3.2.6.2 - option SRID is from the conformance suite

Returns null if the WKT is not a MULTILINESTRING

**Note**

If you are absolutely sure all your WKT geometries are points, don't use this function. It is slower than ST\_GeomFromText since it adds an additional validation step.

This method implements the [OpenGIS Simple Features Implementation Specification for SQL 1.1](#). s3.2.6.2

This method implements the SQL/MM specification. SQL-MM 3: 9.4.4

**Examples**

```
SELECT ST_MLineFromText('MULTILINESTRING((1 2, 3 4), (4 5, 6 7))');
```

**See Also**

[ST\\_GeomFromText](#)

**8.4.32 ST\_MPointFromText**

ST\_MPointFromText — Makes a Geometry from WKT with the given SRID. If SRID is not give, it defaults to 0.

**Synopsis**

```
geometry ST_MPointFromText(text WKT, integer srid);
geometry ST_MPointFromText(text WKT);
```

**Description**

Makes a Geometry from WKT with the given SRID. If SRID is not give, it defaults to 0.

OGC SPEC 3.2.6.2 - option SRID is from the conformance suite

Returns null if the WKT is not a MULTIPOINT

**Note**

If you are absolutely sure all your WKT geometries are points, don't use this function. It is slower than ST\_GeomFromText since it adds an additional validation step.

This method implements the [OpenGIS Simple Features Implementation Specification for SQL 1.1](#). 3.2.6.2

This method implements the SQL/MM specification. SQL-MM 3: 9.2.4

## Examples

```
SELECT ST_MPointFromText('MULTIPOINT(1 2, 3 4)');
SELECT ST_MPointFromText('MULTIPOINT(-70.9590 42.1180, -70.9611 42.1223)', 4326);
```

### 8.4.33 ST\_MPolyFromText

**ST\_MPolyFromText** — Makes a MultiPolygon Geometry from WKT with the given SRID. If SRID is not give, it defaults to 0.

#### Synopsis

```
geometry ST_MPolyFromText(text WKT, integer srid);
geometry ST_MPolyFromText(text WKT);
```

#### Description

Makes a MultiPolygon from WKT with the given SRID. If SRID is not give, it defaults to 0.

OGC SPEC 3.2.6.2 - option SRID is from the conformance suite

Throws an error if the WKT is not a MULTIPOLYGON

#### Note

If you are absolutely sure all your WKT geometries are multipolygons, don't use this function. It is slower than `ST_GeomFromText` since it adds an additional validation step.

This method implements the [OpenGIS Simple Features Implementation Specification for SQL 1.1](#). s3.2.6.2

This method implements the SQL/MM specification. SQL-MM 3: 9.6.4

## Examples

```
SELECT ST_MPolyFromText('MULTIPOLYGON(((0 0 1,20 0 1,20 20 1,0 20 1,0 0 1),(5 5 3,5 7 3,7 7 ←
 3,7 5 3,5 5 3)))');
SELECT ST_MPolyFromText('MULTIPOLYGON(((−70.916 42.1002,−70.9468 42.0946,−70.9765 ←

**8.4.34 ST\_Point**

`ST_Point` — Returns an `ST_Point` with the given coordinate values. OGC alias for `ST_MakePoint`.

**Synopsis**

```
geometry ST_Point(float x_lon, float y_lat);
```

**Description**

Returns an `ST_Point` with the given coordinate values. MM compliant alias for `ST_MakePoint` that takes just an x and y.

This method implements the SQL/MM specification. SQL-MM 3: 6.1.2

**Examples: Geometry**

```
SELECT ST_SetSRID(ST_Point(-71.1043443253471, 42.3150676015829),4326)
```

**Examples: Geography**

```
SELECT CAST(ST_SetSRID(ST_Point(-71.1043443253471, 42.3150676015829),4326) As geography);
```

```
-- the :: is PostgreSQL short-hand for casting.
```

```
SELECT ST_SetSRID(ST_Point(-71.1043443253471, 42.3150676015829),4326)::geography;
```

```
--If your point coordinates are in a different spatial reference from WGS-84 long lat, then ↔
you need to transform before casting
```

```
-- This example we convert a point in Pennsylvania State Plane feet to WGS 84 and then ↔
geography
```

```
SELECT ST_Transform(ST_SetSRID(ST_Point(3637510, 3014852),2273),4326)::geography;
```

**See Also**

Section [4.2.1](#), [ST\\_MakePoint](#), [ST\\_SetSRID](#), [ST\\_Transform](#)

**8.4.35 ST\_PointFromGeoHash**

`ST_PointFromGeoHash` — Return a point from a GeoHash string.

**Synopsis**

```
point ST_PointFromGeoHash(text geohash, integer precision=full_precision_of_geohash);
```

**Description**

Return a point from a GeoHash string. The point represents the center point of the GeoHash.

If no `precision` is specified `ST_PointFromGeoHash` returns a point based on full precision of the input GeoHash string.

If `precision` is specified `ST_PointFromGeoHash` will use that many characters from the GeoHash to create the point.

Availability: 2.1.0

**Examples**

```
SELECT ST_AsText(ST_PointFromGeoHash('9qqj7nmxncgyy4d0dbxqz0'));
 st_astext

POINT(-115.172816 36.114646)

SELECT ST_AsText(ST_PointFromGeoHash('9qqj7nmxncgyy4d0dbxqz0', 4));
 st_astext

POINT(-115.13671875 36.123046875)

SELECT ST_AsText(ST_PointFromGeoHash('9qqj7nmxncgyy4d0dbxqz0', 10));
 st_astext

POINT(-115.172815918922 36.1146435141563)
```

**See Also**

[ST\\_GeoHash](#), [ST\\_Box2dFromGeoHash](#), [ST\\_GeomFromGeoHash](#)

**8.4.36 ST\_PointFromText**

`ST_PointFromText` — Makes a point Geometry from WKT with the given SRID. If SRID is not given, it defaults to unknown.

**Synopsis**

```
geometry ST_PointFromText(text WKT);
geometry ST_PointFromText(text WKT, integer srid);
```

**Description**

Constructs a PostGIS `ST_Geometry` point object from the OGC Well-Known text representation. If SRID is not give, it defaults to unknown (currently 0). If geometry is not a WKT point representation, returns null. If completely invalid WKT, then throws an error.

**Note**

There are 2 variants of `ST_PointFromText` function, the first takes no SRID and returns a geometry with no defined spatial reference system. The second takes a spatial reference id as the second argument and returns an `ST_Geometry` that includes this srid as part of its meta-data. The srid must be defined in the `spatial_ref_sys` table.

**Note**

If you are absolutely sure all your WKT geometries are points, don't use this function. It is slower than `ST_GeomFromText` since it adds an additional validation step. If you are building points from long lat coordinates and care more about performance and accuracy than OGC compliance, use `ST_MakePoint` or OGC compliant alias `ST_Point`.

This method implements the [OpenGIS Simple Features Implementation Specification for SQL 1.1](#). s3.2.6.2 - option SRID is from the conformance suite.

This method implements the SQL/MM specification. SQL-MM 3: 6.1.8

**Examples**

```
SELECT ST_PointFromText('POINT(-71.064544 42.28787)');
SELECT ST_PointFromText('POINT(-71.064544 42.28787)', 4326);
```

**See Also**

[ST\\_GeomFromText](#), [ST\\_MakePoint](#), [ST\\_Point](#), [ST\\_SRID](#)

**8.4.37 ST\_PointFromWKB**

`ST_PointFromWKB` — Makes a geometry from WKB with the given SRID

**Synopsis**

```
geometry ST_GeomFromWKB(bytea geom);
geometry ST_GeomFromWKB(bytea geom, integer srid);
```

**Description**

The `ST_PointFromWKB` function, takes a well-known binary representation of geometry and a Spatial Reference System ID (SRID) and creates an instance of the appropriate geometry type - in this case, a `POINT` geometry. This function plays the role of the Geometry Factory in SQL.

If an SRID is not specified, it defaults to 0. `NULL` is returned if the input `bytea` does not represent a `POINT` geometry.

This method implements the [OpenGIS Simple Features Implementation Specification for SQL 1.1](#). s3.2.7.2

This method implements the SQL/MM specification. SQL-MM 3: 6.1.9

This function supports 3d and will not drop the z-index.

This method supports Circular Strings and Curves

## Examples

```

SELECT
 ST_AsText (
 ST_PointFromWKB (
 ST_AsEWKB ('POINT(2 5)')::geometry)
)
);
st_astext

POINT(2 5)
(1 row)

SELECT
 ST_AsText (
 ST_PointFromWKB (
 ST_AsEWKB ('LINESTRING(2 5, 2 6)')::geometry)
)
);
st_astext

(1 row)

```

### 8.4.38 ST\_Polygon

**ST\_Polygon** — Returns a polygon built from the specified linestring and SRID.

#### Synopsis

geometry **ST\_Polygon**(geometry aLineString, integer srid);

#### Description

Returns a polygon built from the specified linestring and SRID.

#### Note

ST\_Polygon is similar to first version of ST\_MakePolygon except it also sets the spatial ref sys (SRID) of the polygon. Will not work with MULTILINESTRINGS so use LineMerge to merge multilines. Also does not create polygons with holes. Use ST\_MakePolygon for that.

This method implements the [OpenGIS Simple Features Implementation Specification for SQL 1.1](#).

This method implements the SQL/MM specification. SQL-MM 3: 8.3.2

This function supports 3d and will not drop the z-index.

## Examples

```
--a 2d polygon
SELECT ST_Polygon(ST_GeomFromText('LINESTRING(75.15 29.53,77 29,77.6 29.5, 75.15 29.53)'), ←
 4326);

--result--
POLYGON((75.15 29.53,77 29,77.6 29.5,75.15 29.53))
--a 3d polygon
SELECT ST_AsEWKT(ST_Polygon(ST_GeomFromEWKT('LINESTRING(75.15 29.53 1,77 29 1,77.6 29.5 1, ←
 75.15 29.53 1)'), 4326));

result

SRID=4326;POLYGON((75.15 29.53 1,77 29 1,77.6 29.5 1,75.15 29.53 1))
```

### 8.4.39 ST\_PolygonFromText

`ST_PolygonFromText` — Makes a Geometry from WKT with the given SRID. If SRID is not give, it defaults to 0.

#### Synopsis

```
geometry ST_PolygonFromText(text WKT);
geometry ST_PolygonFromText(text WKT, integer srid);
```

#### Description

Makes a Geometry from WKT with the given SRID. If SRID is not give, it defaults to 0. Returns null if WKT is not a polygon.

OGC SPEC 3.2.6.2 - option SRID is from the conformance suite

#### Note

If you are absolutely sure all your WKT geometries are polygons, don't use this function. It is slower than `ST_GeomFromText` since it adds an additional validation step.

This method implements the [OpenGIS Simple Features Implementation Specification for SQL 1.1](#). s3.2.6.2

This method implements the SQL/MM specification. SQL-MM 3: 8.3.6

## Examples

```
SELECT ST_PolygonFromText('POLYGON((-71.1776585052917 42.3902909739571,-71.1776820268866 ←
 42.3903701743239,
-71.1776063012595 42.3903825660754,-71.1775826583081 42.3903033653531,-71.1776585052917 ←
 42.3902909739571))');
st_polygonfromtext

```

```
010300000001000000050000006...
```

```
SELECT ST_PolygonFromText('POINT(1 2)') IS NULL as point_is_notpoly;
```

```
point_is_not_poly
```

```

```

```
t
```

### 8.4.40 ST\_WKBToSQL

**ST\_WKBToSQL** — Return a specified `ST_Geometry` value from Well-Known Binary representation (WKB). This is an alias name for `ST_GeomFromWKB` that takes no `srid`

#### Synopsis

```
geometry ST_WKBToSQL(bytea WKB);
```

#### Description

This method implements the SQL/MM specification. SQL-MM 3: 5.1.36

#### See Also

[ST\\_GeomFromWKB](#)

### 8.4.41 ST\_WKTToSQL

**ST\_WKTToSQL** — Return a specified `ST_Geometry` value from Well-Known Text representation (WKT). This is an alias name for `ST_GeomFromText`

#### Synopsis

```
geometry ST_WKTToSQL(text WKT);
```

#### Description

This method implements the SQL/MM specification. SQL-MM 3: 5.1.34

#### See Also

---

## 8.5 Geometry Accessors

### 8.5.1 GeometryType

**GeometryType** — Returns the type of the geometry as a string. Eg: 'LINESTRING', 'POLYGON', 'MULTIPOINT', etc.

#### Synopsis

```
text GeometryType(geometry geomA);
```

#### Description

Returns the type of the geometry as a string. Eg: 'LINESTRING', 'POLYGON', 'MULTIPOINT', etc.

OGC SPEC s2.1.1.1 - Returns the name of the instantiable subtype of Geometry of which this Geometry instance is a member. The name of the instantiable subtype of Geometry is returned as a string.

#### Note

This function also indicates if the geometry is measured, by returning a string of the form 'POINTM'.

Enhanced: 2.0.0 support for Polyhedral surfaces, Triangles and TIN was introduced.

This method implements the [OpenGIS Simple Features Implementation Specification for SQL 1.1](#).

This method supports Circular Strings and Curves

This function supports 3d and will not drop the z-index.

This function supports Polyhedral surfaces.

This function supports Triangles and Triangulated Irregular Network Surfaces (TIN).

#### Examples

```
SELECT GeometryType(ST_GeomFromText('LINESTRING(77.29 29.07,77.42 29.26,77.27 29.31,77.29 ↵
 29.07)'));
geometrytype

LINESTRING
```

```
SELECT ST_GeometryType(ST_GeomFromEWKT('POLYHEDRALSURFACE(((0 0 0, 0 0 1, 0 1 1, 0 1 0, 0 ↵
 0 0)),
 ((0 0 0, 0 1 0, 1 1 0, 1 0 0, 0 0 0)), ((0 0 0, 1 0 0, 1 0 1, 0 0 1, 0 0 0)),
 ((1 1 0, 1 1 1, 1 0 1, 1 0 0, 1 1 0)),
 ((0 1 0, 0 1 1, 1 1 1, 1 1 0, 0 1 0)), ((0 0 1, 1 0 1, 1 1 1, 0 1 1, 0 0 1)) '));
--result
POLYHEDRALSURFACE
```

```

SELECT GeometryType(geom) as result
FROM
 (SELECT
 ST_GeomFromEWKT('TIN (((
 0 0 0,
 0 0 1,
 0 1 0,
 0 0 0
)), ((
 0 0 0,
 0 1 0,
 1 1 0,
 0 0 0
)))
) AS g;
result

TIN

```

**See Also**[ST\\_GeometryType](#)**8.5.2 ST\_Boundary**

**ST\_Boundary** — Returns the closure of the combinatorial boundary of this Geometry.

**Synopsis**

```
geometry ST_Boundary(geometry geomA);
```

**Description**

Returns the closure of the combinatorial boundary of this Geometry. The combinatorial boundary is defined as described in section 3.12.3.2 of the OGC SPEC. Because the result of this function is a closure, and hence topologically closed, the resulting boundary can be represented using representational geometry primitives as discussed in the OGC SPEC, section 3.12.2.

Performed by the GEOS module

**Note**

Prior to 2.0.0, this function throws an exception if used with `GEOMETRYCOLLECTION`. From 2.0.0 up it will return `NULL` instead (unsupported input).

This method implements the [OpenGIS Simple Features Implementation Specification for SQL 1.1](#). OGC SPEC s2.1.1.1

This method implements the SQL/MM specification. SQL-MM 3: 5.1.14

This function supports 3d and will not drop the z-index.

Enhanced: 2.1.0 support for Triangle was introduced

**Examples**

*Linestring with boundary points overlaid*

```

SELECT ST_Boundary(geom)
FROM (SELECT 'LINESTRING(100 150,50 60, ←
 70 80, 160 170)>:::geometry As geom) As f;

-- ST_AsText output
MULTIPOINT(100 150,160 170)

```

*polygon holes with boundary multilinestring*

```

SELECT ST_Boundary(geom)
FROM (SELECT
'POLYGON ((10 130, 50 190, 110 190, 140 ←
 150, 150 80, 100 10, 20 40, 10 130),
 (70 40, 100 50, 120 80, 80 110, ←
 50 90, 70 40))>:::geometry As geom) As f;

-- ST_AsText output
MULTILINESTRING((10 130,50 190,110 ←
 190,140 150,150 80,100 10,20 40,10 130),
 (70 40,100 50,120 80,80 110,50 ←
 90,70 40))

```

```

SELECT ST_AsText(ST_Boundary(ST_GeomFromText('LINESTRING(1 1,0 0, -1 1)')));
st_astext

MULTIPOINT(1 1,-1 1)

SELECT ST_AsText(ST_Boundary(ST_GeomFromText('POLYGON((1 1,0 0, -1 1, 1 1)'))));
st_astext

LINESTRING(1 1,0 0,-1 1,1 1)

--Using a 3d polygon
SELECT ST_AsEWKT(ST_Boundary(ST_GeomFromEWKT('POLYGON((1 1 1,0 0 1, -1 1 1, 1 1 1)'))));
st_asewkt

LINESTRING(1 1 1,0 0 1,-1 1 1,1 1 1)

--Using a 3d multilinestring
SELECT ST_AsEWKT(ST_Boundary(ST_GeomFromEWKT('MULTILINESTRING((1 1 1,0 0 0.5, -1 1 1),(1 1 ←
 0.5,0 0 0.5, -1 1 0.5, 1 1 0.5)))'));
st_asewkt

MULTIPOINT(-1 1 1,1 1 0.75)

```

**See Also**

[ST\\_AsText](#), [ST\\_ExteriorRing](#), [ST\\_MakePolygon](#)

### 8.5.3 ST\_CoordDim

`ST_CoordDim` — Return the coordinate dimension of the `ST_Geometry` value.

**Synopsis**

```
integer ST_CoordDim(geometry geomA);
```

**Description**

Return the coordinate dimension of the `ST_Geometry` value.

This is the MM compliant alias name for [ST\\_NDims](#)

This method implements the [OpenGIS Simple Features Implementation Specification for SQL 1.1](#).

This method implements the SQL/MM specification. SQL-MM 3: 5.1.3

This method supports Circular Strings and Curves

This function supports 3d and will not drop the z-index.

This function supports Polyhedral surfaces.

This function supports Triangles and Triangulated Irregular Network Surfaces (TIN).

**Examples**

```
SELECT ST_CoordDim('CIRCULARSTRING(1 2 3, 1 3 4, 5 6 7, 8 9 10, 11 12 13)');
---result--
3

SELECT ST_CoordDim(ST_Point(1,2));
--result--
2
```

**See Also**

[ST\\_NDims](#)

### 8.5.4 ST\_Dimension

`ST_Dimension` — The inherent dimension of this Geometry object, which must be less than or equal to the coordinate dimension.

**Synopsis**

integer **ST\_Dimension**(geometry g);

**Description**

The inherent dimension of this Geometry object, which must be less than or equal to the coordinate dimension. OGC SPEC s2.1.1.1 - returns 0 for POINT, 1 for LINESTRING, 2 for POLYGON, and the largest dimension of the components of a GEOMETRYCOLLECTION. If unknown (empty geometry) null is returned.

This method implements the SQL/MM specification. SQL-MM 3: 5.1.2

Enhanced: 2.0.0 support for Polyhedral surfaces and TINs was introduced. No longer throws an exception if given empty geometry.

**Note**

Prior to 2.0.0, this function throws an exception if used with empty geometry.

This function supports Polyhedral surfaces.

This function supports Triangles and Triangulated Irregular Network Surfaces (TIN).

**Examples**

```
SELECT ST_Dimension('GEOMETRYCOLLECTION(LINESTRING(1 1,0 0),POINT(0 0))');
ST_Dimension

1
```

**See Also**

[ST\\_NDims](#)

**8.5.5 ST\_EndPoint**

**ST\_EndPoint** — Returns the last point of a LINESTRING or CIRCULARLINESTRING geometry as a POINT.

**Synopsis**

boolean **ST\_EndPoint**(geometry g);

**Description**

Returns the last point of a LINESTRING geometry as a POINT or NULL if the input parameter is not a LINESTRING.

This method implements the SQL/MM specification. SQL-MM 3: 7.1.4

This function supports 3d and will not drop the z-index.

This method supports Circular Strings and Curves

**Note**

Changed: 2.0.0 no longer works with single geometry multilinestrings. In older versions of PostGIS -- a single line multilinestring would work happily with this function and return the start point. In 2.0.0 it just returns NULL like any other multilinestring. The older behavior was an undocumented feature, but people who assumed they had their data stored as LINESTRING may experience these returning NULL in 2.0 now.

**Examples**

```

postgis=# SELECT ST_AsText(ST_EndPoint('LINESTRING(1 1, 2 2, 3 3)::geometry));
 st_astext

 POINT(3 3)
(1 row)

postgis=# SELECT ST_EndPoint('POINT(1 1)::geometry') IS NULL AS is_null;
 is_null

 t
(1 row)

--3d endpoint
SELECT ST_AsEWKT(ST_EndPoint('LINESTRING(1 1 2, 1 2 3, 0 0 5)'));
 st_asewkt

 POINT(0 0 5)
(1 row)

```

**See Also**

[ST\\_PointN](#), [ST\\_StartPoint](#)

**8.5.6 ST\_Envelope**

**ST\_Envelope** — Returns a geometry representing the double precision (float8) bounding box of the supplied geometry.

**Synopsis**

geometry **ST\_Envelope**(geometry g1);

**Description**

Returns the float8 minimum bounding box for the supplied geometry, as a geometry. The polygon is defined by the corner points of the bounding box ((MINX, MINY), (MINX, MAXY), (MAXX, MAXY), (MAXX, MINY), (MINX, MINY)). (PostGIS will add a ZMIN/ZMAX coordinate as well).

Degenerate cases (vertical lines, points) will return a geometry of lower dimension than POLYGON, ie. POINT or LINESTRING.

Availability: 1.5.0 behavior changed to output double precision instead of float4

This method implements the [OpenGIS Simple Features Implementation Specification for SQL 1.1](#). s2.1.1.1

This method implements the SQL/MM specification. SQL-MM 3: 5.1.15

## Examples

```

SELECT ST_AsText(ST_Envelope('POINT(1 3)::geometry'));
 st_astext

POINT(1 3)
(1 row)

SELECT ST_AsText(ST_Envelope('LINESTRING(0 0, 1 3)::geometry'));
 st_astext

POLYGON((0 0,0 3,1 3,1 0,0 0))
(1 row)

SELECT ST_AsText(ST_Envelope('POLYGON((0 0, 0 1, 1.0000001 1, 1.0000001 0, 0 0))::geometry ←
));
 st_astext

POLYGON((0 0,0 1,1.00000011920929 1,1.00000011920929 0,0 0))
(1 row)
SELECT ST_AsText(ST_Envelope('POLYGON((0 0, 0 1, 1.0000000001 1, 1.0000000001 0, 0 0))':: ←
 geometry));
 st_astext

POLYGON((0 0,0 1,1.00000011920929 1,1.00000011920929 0,0 0))
(1 row)

SELECT Box3D(geom), Box2D(geom), ST_AsText(ST_Envelope(geom)) As envelopewkt
FROM (SELECT 'POLYGON((0 0, 0 1000012333334.34545678, 1.0000001 1, 1.0000001 0, 0 0))':: ←
 geometry As geom) As foo;

```

## See Also

[Box2D](#), [Box3D](#)

## 8.5.7 ST\_BoundingDiagonal

`ST_BoundingDiagonal` — Returns the diagonal of the supplied geometry's bounding box.

### Synopsis

```
geometry ST_BoundingDiagonal(geometry geom, boolean fits=false);
```

### Description

Returns the diagonal of the supplied geometry's bounding box as linestring. If the input geometry is empty, the diagonal line is also empty, otherwise it is a 2-points linestring with minimum values of each dimension in its start point and maximum values in its end point.

The returned linestring geometry always retains SRID and dimensionality (Z and M presence) of the input geometry.

The `fits` parameter specifies if the best fit is needed. If false, the diagonal of a somewhat larger bounding box can be accepted (is faster to obtain for geometries with a lot of vertices). In any case the bounding box of the returned diagonal line always covers the input geometry.

**Note**

In degenerate cases (a single vertex in input) the returned linestring will be topologically invalid (no interior). This does not make the return semantically invalid.

Availability: 2.2.0

This function supports 3d and will not drop the z-index.

This function supports M coordinates.

**Examples**

```
-- Get the minimum X in a buffer around a point
SELECT ST_X(ST_StartPoint(ST_BoundingDiagonal(
 ST_Buffer(ST_MakePoint(0,0),10)
)));
st_x

-10
```

**See Also**

[ST\\_StartPoint](#), [ST\\_EndPoint](#), [ST\\_X](#), [ST\\_Y](#), [ST\\_Z](#), [ST\\_M](#), &&&

**8.5.8 ST\_ExteriorRing**

`ST_ExteriorRing` — Returns a line string representing the exterior ring of the `POLYGON` geometry. Return `NULL` if the geometry is not a polygon. Will not work with `MULTIPOLYGON`

**Synopsis**

```
geometry ST_ExteriorRing(geometry a_polygon);
```

**Description**

Returns a line string representing the exterior ring of the `POLYGON` geometry. Return `NULL` if the geometry is not a polygon.

**Note**

Only works with `POLYGON` geometry types

This method implements the [OpenGIS Simple Features Implementation Specification for SQL 1.1](#). 2.1.5.1

This method implements the SQL/MM specification. SQL-MM 3: 8.2.3, 8.3.3

This function supports 3d and will not drop the z-index.

## Examples

```
--If you have a table of polygons
SELECT gid, ST_ExteriorRing(the_geom) AS ering
FROM sometable;

--If you have a table of MULTIPOLYGONS
--and want to return a MULTILINESTRING composed of the exterior rings of each polygon
SELECT gid, ST_Collect(ST_ExteriorRing(the_geom)) AS erings
 FROM (SELECT gid, (ST_Dump(the_geom)).geom As the_geom
 FROM sometable) As foo
GROUP BY gid;

--3d Example
SELECT ST_AsEWKT(
 ST_ExteriorRing(
 ST_GeomFromEWKT('POLYGON((0 0 1, 1 1 1, 1 2 1, 1 1 1, 0 0 1))')
)
);

st_asewkt

LINESTRING(0 0 1,1 1 1,1 2 1,1 1 1,0 0 1)
```

## 8.5.9 ST\_GeometryN

**ST\_GeometryN** — Return the 1-based Nth geometry if the geometry is a GEOMETRYCOLLECTION, (MULTI)POINT, (MULTI)LINestring, MULTICURVE or (MULTI)POLYGON, POLYHEDRALSURFACE Otherwise, return NULL.

### Synopsis

geometry **ST\_GeometryN**(geometry geomA, integer n);

### Description

Return the 1-based Nth geometry if the geometry is a GEOMETRYCOLLECTION, (MULTI)POINT, (MULTI)LINestring, MULTICURVE or (MULTI)POLYGON, POLYHEDRALSURFACE Otherwise, return NULL

#### Note

Index is 1-based as for OGC specs since version 0.8.0. Previous versions implemented this as 0-based instead.

---

#### Note

If you want to extract all geometries, of a geometry, **ST\_Dump** is more efficient and will also work for singular geoms.

---

Enhanced: 2.0.0 support for Polyhedral surfaces, Triangles and TIN was introduced.

Changed: 2.0.0 Prior versions would return NULL for singular geometries. This was changed to return the geometry for ST\_GeometryN(...,1) case.

This method implements the [OpenGIS Simple Features Implementation Specification for SQL 1.1](#).

This method implements the SQL/MM specification. SQL-MM 3: 9.1.5

This function supports 3d and will not drop the z-index.

This method supports Circular Strings and Curves

This function supports Polyhedral surfaces.

This function supports Triangles and Triangulated Irregular Network Surfaces (TIN).

### Standard Examples

```
--Extracting a subset of points from a 3d multipoint
SELECT n, ST_AsEWKT(ST_GeometryN(the_geom, n)) As geomewkt
FROM (
VALUES (ST_GeomFromEWKT('MULTIPOINT(1 2 7, 3 4 7, 5 6 7, 8 9 10)')),
(ST_GeomFromEWKT('MULTICURVE(CIRCULARSTRING(2.5 2.5,4.5 2.5, 3.5 3.5), (10 11, 12 11))'))
)As foo(the_geom)
CROSS JOIN generate_series(1,100) n
WHERE n <= ST_NumGeometries(the_geom);
```

| n | geomewkt                                |
|---|-----------------------------------------|
| 1 | POINT(1 2 7)                            |
| 2 | POINT(3 4 7)                            |
| 3 | POINT(5 6 7)                            |
| 4 | POINT(8 9 10)                           |
| 1 | CIRCULARSTRING(2.5 2.5,4.5 2.5,3.5 3.5) |
| 2 | LINestring(10 11,12 11)                 |

```
--Extracting all geometries (useful when you want to assign an id)
SELECT gid, n, ST_GeometryN(the_geom, n)
FROM sometable CROSS JOIN generate_series(1,100) n
WHERE n <= ST_NumGeometries(the_geom);
```

### Polyhedral Surfaces, TIN and Triangle Examples

```
-- Polyhedral surface example
-- Break a Polyhedral surface into its faces
SELECT ST_AsEWKT(ST_GeometryN(p_geom,3)) As geom_ewkt
FROM (SELECT ST_GeomFromEWKT('POLYHEDRALSURFACE(
((0 0 0, 0 0 1, 0 1 1, 0 1 0, 0 0 0)),

**8.5.10 ST\_GeometryType**

`ST_GeometryType` — Return the geometry type of the `ST_Geometry` value.

**Synopsis**

```
text ST_GeometryType(geometry g1);
```

**Description**

Returns the type of the geometry as a string. EG: 'ST\_Linestring', 'ST\_Polygon', 'ST\_MultiPolygon' etc. This function differs from `GeometryType(geometry)` in the case of the string and ST in front that is returned, as well as the fact that it will not indicate whether the geometry is measured.

Enhanced: 2.0.0 support for Polyhedral surfaces was introduced.

This method implements the SQL/MM specification. SQL-MM 3: 5.1.4

This function supports 3d and will not drop the z-index.

This function supports Polyhedral surfaces.

## Examples

```
SELECT ST_GeometryType(ST_GeomFromText('LINESTRING(77.29 29.07,77.42 29.26,77.27 29.31,77.29 29.07)'));
--result
ST_LineString
```

```
SELECT ST_GeometryType(ST_GeomFromEWKT('POLYHEDRALSURFACE(((0 0 0, 0 0 1, 0 1 1, 0 1 0, 0 0 0)),
((0 0 0, 0 1 0, 1 1 0, 1 0 0, 0 0 0)), ((0 0 0, 1 0 0, 1 0 1, 0 0 1, 0 0 0)),
((1 1 0, 1 1 1, 1 0 1, 1 0 0, 1 1 0)),
((0 1 0, 0 1 1, 1 1 1, 1 1 0, 0 1 0)), ((0 0 1, 1 0 1, 1 1 1, 0 1 1, 0 0 1)))'));
--result
ST_PolyhedralSurface
```

```
SELECT ST_GeometryType(ST_GeomFromEWKT('POLYHEDRALSURFACE(((0 0 0, 0 0 1, 0 1 1, 0 1 0, 0 0 0)),
((0 0 0, 0 1 0, 1 1 0, 1 0 0, 0 0 0)), ((0 0 0, 1 0 0, 1 0 1, 0 0 1, 0 0 0)),
((1 1 0, 1 1 1, 1 0 1, 1 0 0, 1 1 0)),
((0 1 0, 0 1 1, 1 1 1, 1 1 0, 0 1 0)), ((0 0 1, 1 0 1, 1 1 1, 0 1 1, 0 0 1)))'));
--result
ST_PolyhedralSurface
```

```
SELECT ST_GeometryType(geom) as result
FROM
 (SELECT
 ST_GeomFromEWKT('TIN (((
 0 0 0,
 0 0 1,
 0 1 0,
 0 0 0
)), ((
 0 0 0,
 0 1 0,
 1 1 0,
 0 0 0
))
)') AS geom
) AS g;
result

ST_Tin
```

### 8.5.11 ST\_InteriorRingN

**ST\_InteriorRingN** — Return the Nth interior linestring ring of the polygon geometry. Return NULL if the geometry is not a polygon or the given N is out of range.

#### Synopsis

```
geometry ST_InteriorRingN(geometry a_polygon, integer n);
```

## Description

Return the Nth interior linestring ring of the polygon geometry. Return NULL if the geometry is not a polygon or the given N is out of range. index starts at 1.

### Note

This will not work for MULTIPOLYGONS. Use in conjunction with ST\_Dump for MULTIPOLYGONS

This method implements the [OpenGIS Simple Features Implementation Specification for SQL 1.1](#).

This method implements the SQL/MM specification. SQL-MM 3: 8.2.6, 8.3.5

This function supports 3d and will not drop the z-index.

## Examples

```
SELECT ST_AsText(ST_InteriorRingN(the_geom, 1)) As the_geom
FROM (SELECT ST_BuildArea(
 ST_Collect(ST_Buffer(ST_Point(1,2), 20,3),
 ST_Buffer(ST_Point(1, 2), 10,3))) As the_geom
) as foo
```

### 8.5.12 ST\_IsClosed

**ST\_IsClosed** — Returns TRUE if the LINESRING's start and end points are coincident. For Polyhedral surface is closed (volumetric).

## Synopsis

boolean **ST\_IsClosed**(geometry g);

## Description

Returns TRUE if the LINESRING's start and end points are coincident. For Polyhedral Surfaces, it tells you if the surface is areal (open) or volumetric (closed).

This method implements the [OpenGIS Simple Features Implementation Specification for SQL 1.1](#).

This method implements the SQL/MM specification. SQL-MM 3: 7.1.5, 9.3.3

### Note

SQL-MM defines the result of ST\_IsClosed(NULL) to be 0, while PostGIS returns NULL.

This function supports 3d and will not drop the z-index.

This method supports Circular Strings and Curves

Enhanced: 2.0.0 support for Polyhedral surfaces was introduced.

This function supports Polyhedral surfaces.

### Line String and Point Examples

```

postgis=# SELECT ST_IsClosed('LINESTRING(0 0, 1 1)::geometry);
 st_isclosed

f
(1 row)

postgis=# SELECT ST_IsClosed('LINESTRING(0 0, 0 1, 1 1, 0 0)::geometry);
 st_isclosed

t
(1 row)

postgis=# SELECT ST_IsClosed('MULTILINESTRING((0 0, 0 1, 1 1, 0 0),(0 0, 1 1))::geometry);
 st_isclosed

f
(1 row)

postgis=# SELECT ST_IsClosed('POINT(0 0)::geometry);
 st_isclosed

t
(1 row)

postgis=# SELECT ST_IsClosed('MULTIPOINT((0 0), (1 1))::geometry);
 st_isclosed

t
(1 row)

```

### Polyhedral Surface Examples

```

-- A cube --
SELECT ST_IsClosed(ST_GeomFromEWKT('POLYHEDRALSURFACE(((0 0 0, 0 0 1, 0 1 1, 0 1 0, 0 0 0) ←
0 0)),
((0 0 0, 0 1 0, 1 1 0, 1 0 0, 0 0 0)), ((0 0 0, 1 0 0, 1 0 1, 0 0 1, 0 0 0)),
((1 1 0, 1 1 1, 1 0 1, 1 0 0, 1 1 0)),
((0 1 0, 0 1 1, 1 1 1, 1 1 0, 0 1 0)), ((0 0 1, 1 0 1, 1 1 1, 0 1 1, 0 0 1)))'));

 st_isclosed

t

-- Same as cube but missing a side --
SELECT ST_IsClosed(ST_GeomFromEWKT('POLYHEDRALSURFACE(((0 0 0, 0 0 1, 0 1 1, 0 1 0, 0 0 0) ←
0)),

```

```
((0 0 0, 0 1 0, 1 1 0, 1 0 0, 0 0 0)), ((0 0 0, 1 0 0, 1 0 1, 0 0 1, 0 0 0)),
((1 1 0, 1 1 1, 1 0 1, 1 0 0, 1 1 0)),
((0 1 0, 0 1 1, 1 1 1, 1 1 0, 0 1 0)))'));
```

```
stisclosed
```

```
f
```

### 8.5.13 ST\_IsCollection

**ST\_IsCollection** — Returns TRUE if the argument is a collection (MULTI\*, GEOMETRYCOLLECTION, ...)

#### Synopsis

```
boolean ST_IsCollection(geometry g);
```

#### Description

Returns TRUE if the geometry type of the argument is either:

- GEOMETRYCOLLECTION
- MULTI{POINT,POLYGON,LINestring,CURVE,SURFACE}
- COMPOUNDCURVE

#### Note

This function analyzes the type of the geometry. This means that it will return TRUE on collections that are empty or that contain a single element.

This function supports 3d and will not drop the z-index.

This method supports Circular Strings and Curves

#### Examples

```
postgis=# SELECT ST_IsCollection('LINESTRING(0 0, 1 1)::geometry);
st_iscollection
```

```
f
(1 row)
```

```
postgis=# SELECT ST_IsCollection('MULTIPOINT EMPTY)::geometry);
st_iscollection
```

```
t
```

```
(1 row)

postgis=# SELECT ST_IsCollection('MULTIPOINT((0 0))'::geometry);
 st_iscollection

 t
(1 row)

postgis=# SELECT ST_IsCollection('MULTIPOINT((0 0), (42 42))'::geometry);
 st_iscollection

 t
(1 row)

postgis=# SELECT ST_IsCollection('GEOMETRYCOLLECTION(POINT(0 0))'::geometry);
 st_iscollection

 t
(1 row)
```

**See Also**[ST\\_NumGeometries](#)**8.5.14 ST\_IsEmpty**

**ST\_IsEmpty** — Returns true if this Geometry is an empty geometrycollection, polygon, point etc.

**Synopsis**

boolean **ST\_IsEmpty**(geometry geomA);

**Description**

Returns true if this Geometry is an empty geometry. If true, then this Geometry represents an empty geometry collection, polygon, point etc.

**Note**

SQL-MM defines the result of `ST_IsEmpty(NULL)` to be 0, while PostGIS returns NULL.

This method implements the [OpenGIS Simple Features Implementation Specification for SQL 1.1](#). s2.1.1.1

This method implements the SQL/MM specification. SQL-MM 3: 5.1.7

This method supports Circular Strings and Curves

**Warning**

Changed: 2.0.0 In prior versions of PostGIS `ST_GeomFromText('GEOMETRYCOLLECTION(EMPTY)')` was allowed. This is now illegal in PostGIS 2.0.0 to better conform with SQL/MM standards

## Examples

```
SELECT ST_IsEmpty(ST_GeomFromText('GEOMETRYCOLLECTION EMPTY'));
 st_isempty

t
(1 row)

SELECT ST_IsEmpty(ST_GeomFromText('POLYGON EMPTY'));
 st_isempty

t
(1 row)

SELECT ST_IsEmpty(ST_GeomFromText('POLYGON((1 2, 3 4, 5 6, 1 2))'));

 st_isempty

f
(1 row)

SELECT ST_IsEmpty(ST_GeomFromText('POLYGON((1 2, 3 4, 5 6, 1 2))) = false;
?column?

t
(1 row)

SELECT ST_IsEmpty(ST_GeomFromText('CIRCULARSTRING EMPTY'));
 st_isempty

t
(1 row)
```

### 8.5.15 ST\_IsRing

**ST\_IsRing** — Returns TRUE if this LINESTRING is both closed and simple.

#### Synopsis

boolean **ST\_IsRing**(geometry g);

#### Description

Returns TRUE if this LINESTRING is both **ST\_IsClosed** ( $ST\_StartPoint((g)) \sim ST\_Endpoint((g))$ ) and **ST\_IsSimple** (does not self intersect).

This method implements the [OpenGIS Simple Features Implementation Specification for SQL 1.1](#). 2.1.5.1

This method implements the SQL/MM specification. SQL-MM 3: 7.1.6

#### Note

SQL-MM defines the result of **ST\_IsRing** (NULL) to be 0, while PostGIS returns NULL.

## Examples

```
SELECT ST_IsRing(the_geom), ST_IsClosed(the_geom), ST_IsSimple(the_geom)
FROM (SELECT 'LINESTRING(0 0, 0 1, 1 1, 1 0, 0 0)::geometry AS the_geom) AS foo;
 st_isring | st_isclosed | st_issimple
-----+-----+-----
t | t | t
(1 row)

SELECT ST_IsRing(the_geom), ST_IsClosed(the_geom), ST_IsSimple(the_geom)
FROM (SELECT 'LINESTRING(0 0, 0 1, 1 0, 1 1, 0 0)::geometry AS the_geom) AS foo;
 st_isring | st_isclosed | st_issimple
-----+-----+-----
f | t | f
(1 row)
```

### 8.5.16 ST\_IsSimple

**ST\_IsSimple** — Returns (TRUE) if this Geometry has no anomalous geometric points, such as self intersection or self tangency.

#### Synopsis

boolean **ST\_IsSimple**(geometry geomA);

#### Description

Returns true if this Geometry has no anomalous geometric points, such as self intersection or self tangency. For more information on the OGC's definition of geometry simplicity and validity, refer to "[Ensuring OpenGIS compliancy of geometries](#)"

#### Note

SQL-MM defines the result of `ST_IsSimple(NULL)` to be 0, while PostGIS returns NULL.

This method implements the [OpenGIS Simple Features Implementation Specification for SQL 1.1](#). s2.1.1.1

This method implements the SQL/MM specification. SQL-MM 3: 5.1.8

This function supports 3d and will not drop the z-index.

## Examples

```
SELECT ST_IsSimple(ST_GeomFromText('POLYGON((1 2, 3 4, 5 6, 1 2))'));
 st_issimple

t
(1 row)
```

```
SELECT ST_IsSimple(ST_GeomFromText('LINESTRING(1 1,2 2,2 3.5,1 3,1 2,2 1)'));
st_issimple

f
(1 row)
```

## See Also

[ST\\_IsValid](#)

### 8.5.17 ST\_IsValid

`ST_IsValid` — Returns `true` if the `ST_Geometry` is well formed.

#### Synopsis

```
boolean ST_IsValid(geometry g);
boolean ST_IsValid(geometry g, integer flags);
```

#### Description

Test if an `ST_Geometry` value is well formed. For geometries that are invalid, the PostgreSQL NOTICE will provide details of why it is not valid. For more information on the OGC's definition of geometry simplicity and validity, refer to "[Ensuring OpenGIS compliancy of geometries](#)"

#### Note

SQL-MM defines the result of `ST_IsValid(NULL)` to be 0, while PostGIS returns NULL.

The version accepting flags is available starting with 2.0.0 and requires GEOS  $\geq$  3.3.0. Such version does not print a NOTICE explaining the invalidity. Allowed `flags` are documented in [ST\\_IsValidDetail](#).

This method implements the [OpenGIS Simple Features Implementation Specification for SQL 1.1](#).

This method implements the SQL/MM specification. SQL-MM 3: 5.1.9

#### Note

Neither OGC-SFS nor SQL-MM specifications include a flag argument for `ST_IsValid`. The flag is a PostGIS extension.

#### Examples

```
SELECT ST_IsValid(ST_GeomFromText('LINESTRING(0 0, 1 1)')) As good_line,
 ST_IsValid(ST_GeomFromText('POLYGON((0 0, 1 1, 1 2, 1 1, 0 0))')) As bad_poly
--results
NOTICE: Self-intersection at or near point 0 0
good_line | bad_poly
-----+-----
t | f
```

**See Also**

[ST\\_IsSimple](#), [ST\\_IsValidReason](#), [ST\\_IsValidDetail](#), [ST\\_Summary](#)

**8.5.18 ST\_IsValidReason**

`ST_IsValidReason` — Returns text stating if a geometry is valid or not and if not valid, a reason why.

**Synopsis**

```
text ST_IsValidReason(geometry geomA);
text ST_IsValidReason(geometry geomA, integer flags);
```

**Description**

Returns text stating if a geometry is valid or not and if not valid, a reason why.

Useful in combination with `ST_IsValid` to generate a detailed report of invalid geometries and reasons.

Allowed flags are documented in [ST\\_IsValidDetail](#).

Availability: 1.4 - requires GEOS >= 3.1.0.

Availability: 2.0 - requires GEOS >= 3.3.0 for the version taking flags.

**Examples**

```
--First 3 Rejects from a successful quintuplet experiment
SELECT gid, ST_IsValidReason(the_geom) as validity_info
FROM
 (SELECT ST_MakePolygon(ST_ExteriorRing(e.buff), ST_Accum(f.line)) As the_geom, gid

## 8.5.19 ST\_IsValidDetail

**ST\_IsValidDetail** — Returns a valid\_detail (valid,reason,location) row stating if a geometry is valid or not and if not valid, a reason why and a location where.

### Synopsis

```
valid_detail ST_IsValidDetail(geometry geom);
valid_detail ST_IsValidDetail(geometry geom, integer flags);
```

### Description

Returns a valid\_detail row, formed by a boolean (valid) stating if a geometry is valid, a varchar (reason) stating a reason why it is invalid and a geometry (location) pointing out where it is invalid.

Useful to substitute and improve the combination of [ST\\_IsValid](#) and [ST\\_IsValidReason](#) to generate a detailed report of invalid geometries.

The 'flags' argument is a bitfield. It can have the following values:

- 1: Consider self-intersecting rings forming holes as valid. This is also know as "the ESRI flag". Note that this is against the OGC model.

Availability: 2.0.0 - requires GEOS >= 3.3.0.

### Examples

```
--First 3 Rejects from a successful quintuplet experiment
SELECT gid, reason(ST_IsValidDetail(the_geom)), ST_AsText(location(ST_IsValidDetail(↵
 the_geom))) as location
FROM
(SELECT ST_MakePolygon(ST_ExteriorRing(e.buff), ST_Accum(f.line)) As the_geom, gid
FROM (SELECT ST_Buffer(ST_MakePoint(x1*10,y1), z1) As buff, x1*10 + y1*100 + z1*1000 As gid
FROM generate_series(-4,6) x1
CROSS JOIN generate_series(2,5) y1
CROSS JOIN generate_series(1,8) z1
WHERE x1 > y1*0.5 AND z1 < x1*y1) As e
INNER JOIN (SELECT ST_Translate(ST_ExteriorRing(ST_Buffer(ST_MakePoint(x1*10,y1), z1)),y1 ↵
 *1, z1*2) As line
FROM generate_series(-3,6) x1
CROSS JOIN generate_series(2,5) y1
CROSS JOIN generate_series(1,10) z1
WHERE x1 > y1*0.75 AND z1 < x1*y1) As f
ON (ST_Area(e.buff) > 78 AND ST_Contains(e.buff, f.line))
GROUP BY gid, e.buff) As quintuplet_experiment
WHERE ST_IsValid(the_geom) = false
ORDER BY gid
LIMIT 3;
```

```

gid | reason | location
-----+-----+-----

**8.5.20 ST\_M**

**ST\_M** — Return the M coordinate of the point, or NULL if not available. Input must be a point.

**Synopsis**

```
float ST_M(geometry a_point);
```

**Description**

Return the M coordinate of the point, or NULL if not available. Input must be a point.

**Note**

This is not (yet) part of the OGC spec, but is listed here to complete the point coordinate extractor function list.

This method implements the [OpenGIS Simple Features Implementation Specification for SQL 1.1](#).

This method implements the SQL/MM specification.

This function supports 3d and will not drop the z-index.

**Examples**

```

SELECT ST_M(ST_GeomFromEWKT('POINT(1 2 3 4)'));
 st_m

 4
(1 row)

```

**See Also**

[ST\\_GeomFromEWKT](#), [ST\\_X](#), [ST\\_Y](#), [ST\\_Z](#)

**8.5.21 ST\_NDims**

`ST_NDims` — Returns coordinate dimension of the geometry as a small int. Values are: 2,3 or 4.

**Synopsis**

```
integer ST_NDims(geometry g1);
```

**Description**

Returns the coordinate dimension of the geometry. PostGIS supports 2 - (x,y) , 3 - (x,y,z) or 2D with measure - x,y,m, and 4 - 3D with measure space x,y,z,m

This function supports 3d and will not drop the z-index.

**Examples**

```
SELECT ST_NDims(ST_GeomFromText('POINT(1 1)')) As d2point,
 ST_NDims(ST_GeomFromEWKT('POINT(1 1 2)')) As d3point,
 ST_NDims(ST_GeomFromEWKT('POINTM(1 1 0.5)')) As d2pointm;
```

```

d2point | d3point | d2pointm
-----+-----+-----
 2 | 3 | 3
```

**See Also**

[ST\\_CoordDim](#), [ST\\_Dimension](#), [ST\\_GeomFromEWKT](#)

**8.5.22 ST\_NPoints**

`ST_NPoints` — Return the number of points (vertexes) in a geometry.

**Synopsis**

```
integer ST_NPoints(geometry g1);
```

**Description**

Return the number of points in a geometry. Works for all geometries.

Enhanced: 2.0.0 support for Polyhedral surfaces was introduced.

**Note**

Prior to 1.3.4, this function crashes if used with geometries that contain CURVES. This is fixed in 1.3.4+

This function supports 3d and will not drop the z-index.

This method supports Circular Strings and Curves

This function supports Polyhedral surfaces.

### Examples

```
SELECT ST_NPoints(ST_GeomFromText('LINESTRING(77.29 29.07,77.42 29.26,77.27 29.31,77.29 ↵
 29.07)'));
--result
4

--Polygon in 3D space
SELECT ST_NPoints(ST_GeomFromEWKT('LINESTRING(77.29 29.07 1,77.42 29.26 0,77.27 29.31 ↵
 -1,77.29 29.07 3)'));
--result
4
```

### See Also

[ST\\_NumPoints](#)

## 8.5.23 ST\_NRings

ST\_NRings — If the geometry is a polygon or multi-polygon returns the number of rings.

### Synopsis

integer **ST\_NRings**(geometry geomA);

### Description

If the geometry is a polygon or multi-polygon returns the number of rings. Unlike NumInteriorRings, it counts the outer rings as well.

This function supports 3d and will not drop the z-index.

This method supports Circular Strings and Curves

### Examples

```
SELECT ST_NRings(the_geom) As Nrings, ST_NumInteriorRings(the_geom) As ninterrings
 FROM (SELECT ST_GeomFromText('POLYGON((1 2, 3 4, 5 6, 1 2))') As the_geom) As foo ↵
 ;
 nrings | ninterrings
-----+-----
 1 | 0
(1 row)
```

**See Also**[ST\\_NumInteriorRings](#)**8.5.24 ST\_NumGeometries**

**ST\_NumGeometries** — If geometry is a **GEOMETRYCOLLECTION** (or **MULTI\***) return the number of geometries, for single geometries will return 1, otherwise return **NULL**.

**Synopsis**

```
integer ST_NumGeometries(geometry geom);
```

**Description**

Returns the number of Geometries. If geometry is a **GEOMETRYCOLLECTION** (or **MULTI\***) return the number of geometries, for single geometries will return 1, otherwise return **NULL**.

Enhanced: 2.0.0 support for Polyhedral surfaces, Triangles and TIN was introduced.

Changed: 2.0.0 In prior versions this would return **NULL** if the geometry was not a collection/**MULTI** type. 2.0.0+ now returns 1 for single geometries e.g **POLYGON**, **LINestring**, **POINT**.

This method implements the SQL/MM specification. SQL-MM 3: 9.1.4

This function supports 3d and will not drop the z-index.

This function supports Polyhedral surfaces.

This function supports Triangles and Triangulated Irregular Network Surfaces (TIN).

**Examples**

```
--Prior versions would have returned NULL for this -- in 2.0.0 this returns 1
SELECT ST_NumGeometries(ST_GeomFromText('LINestring(77.29 29.07,77.42 29.26,77.27 ↵
 29.31,77.29 29.07)'));
--result
1

--Geometry Collection Example - multis count as one geom in a collection
SELECT ST_NumGeometries(ST_GeomFromEWKT('GEOMETRYCOLLECTION(MULTIPOINT(-2 3 , -2 2),
LINestring(5 5 ,10 10),
POLYGON((-7 4.2,-7.1 5,-7.1 4.3,-7 4.2))'));
--result
3
```

**See Also**[ST\\_GeometryN](#), [ST\\_Multi](#)**8.5.25 ST\_NumInteriorRings**

**ST\_NumInteriorRings** — Return the number of interior rings of a polygon geometry.

## Synopsis

integer **ST\_NumInteriorRings**(geometry a\_polygon);

## Description

Return the number of interior rings of a polygon geometry. Return NULL if the geometry is not a polygon.

This method implements the SQL/MM specification. SQL-MM 3: 8.2.5

Changed: 2.0.0 - in prior versions it would allow passing a MULTIPOLYGON, returning the number of interior rings of first POLYGON.

## Examples

```
--If you have a regular polygon
SELECT gid, field1, field2, ST_NumInteriorRings(the_geom) AS numholes
FROM sometable;

--If you have multipolygons
--And you want to know the total number of interior rings in the MULTIPOLYGON
SELECT gid, field1, field2, SUM(ST_NumInteriorRings(the_geom)) AS numholes
FROM (SELECT gid, field1, field2, (ST_Dump(the_geom)).geom As the_geom
 FROM sometable) As foo
GROUP BY gid, field1, field2;
```

## See Also

[ST\\_NumInteriorRing](#)

### 8.5.26 ST\_NumInteriorRing

**ST\_NumInteriorRing** — Return the number of interior rings of a polygon in the geometry. Synonym for **ST\_NumInteriorRings**.

## Synopsis

integer **ST\_NumInteriorRing**(geometry a\_polygon);

## See Also

[ST\\_NumInteriorRings](#)

### 8.5.27 ST\_NumPatches

**ST\_NumPatches** — Return the number of faces on a Polyhedral Surface. Will return null for non-polyhedral geometries.

## Synopsis

integer **ST\_NumPatches**(geometry g1);

---

## Description

Return the number of faces on a Polyhedral Surface. Will return null for non-polyhedral geometries. This is an alias for `ST_NumGeometries` to support MM naming. Faster to use `ST_NumGeometries` if you don't care about MM convention.

Availability: 2.0.0

This function supports 3d and will not drop the z-index.

This method implements the [OpenGIS Simple Features Implementation Specification for SQL 1.1](#).

This method implements the SQL/MM specification. SQL-MM 3: ?

This function supports Polyhedral surfaces.

## Examples

```
SELECT ST_NumPatches(ST_GeomFromEWKT('POLYHEDRALSURFACE(((0 0 0, 0 0 1, 0 1 1, 0 1 0, 0 0 ←
0)),
((0 0 0, 0 1 0, 1 1 0, 1 0 0, 0 0 0)), ((0 0 0, 1 0 0, 1 0 1, 0 0 1, 0 0 0)),
((1 1 0, 1 1 1, 1 0 1, 1 0 0, 1 1 0)),
((0 1 0, 0 1 1, 1 1 1, 1 1 0, 0 1 0)), ((0 0 1, 1 0 1, 1 1 1, 0 1 1, 0 0 1)))'));
--result
6
```

## See Also

[ST\\_GeomFromEWKT](#), [ST\\_NumGeometries](#)

## 8.5.28 ST\_NumPoints

`ST_NumPoints` — Return the number of points in an `ST_LineString` or `ST_CircularString` value.

### Synopsis

```
integer ST_NumPoints(geometry g1);
```

### Description

Return the number of points in an `ST_LineString` or `ST_CircularString` value. Prior to 1.4 only works with `LineStrings` as the specs state. From 1.4 forward this is an alias for `ST_NPoints` which returns number of vertexes for not just line strings. Consider using `ST_NPoints` instead which is multi-purpose and works with many geometry types.

This method implements the [OpenGIS Simple Features Implementation Specification for SQL 1.1](#).

This method implements the SQL/MM specification. SQL-MM 3: 7.2.4

## Examples

```
SELECT ST_NumPoints(ST_GeomFromText('LINESTRING(77.29 29.07,77.42 29.26,77.27 29.31,77.29 29.07)'));
--result
4
```

## See Also

[ST\\_NPoints](#)

## 8.5.29 ST\_PatchN

**ST\_PatchN** — Return the 1-based Nth geometry (face) if the geometry is a POLYHEDRALSURFACE, POLYHEDRALSURFACEM. Otherwise, return NULL.

### Synopsis

geometry **ST\_PatchN**(geometry geomA, integer n);

### Description

>Return the 1-based Nth geometry (face) if the geometry is a POLYHEDRALSURFACE, POLYHEDRALSURFACEM. Otherwise, return NULL. This returns the same answer as ST\_GeometryN for Polyhedral Surfaces. Using ST\_GeometryN is faster.

#### Note

Index is 1-based.

#### Note

If you want to extract all geometries, of a geometry, ST\_Dump is more efficient.

Availability: 2.0.0

This method implements the SQL/MM specification. SQL-MM 3: ?

This function supports 3d and will not drop the z-index.

This function supports Polyhedral surfaces.

## Examples

```

--Extract the 2nd face of the polyhedral surface
SELECT ST_AsEWKT(ST_PatchN(geom, 2)) As geomewkt
FROM (
VALUES (ST_GeomFromEWKT('POLYHEDRALSURFACE(((0 0 0, 0 0 1, 0 1 1, 0 1 0, 0 0 0)),
((0 0 0, 0 1 0, 1 1 0, 1 0 0, 0 0 0)), ((0 0 0, 1 0 0, 1 0 1, 0 0 1, 0 0 0)),
((1 1 0, 1 1 1, 1 0 1, 1 0 0, 1 1 0)),
((0 1 0, 0 1 1, 1 1 1, 1 1 0, 0 1 0)), ((0 0 1, 1 0 1, 1 1 1, 0 1 1, 0 0 1)))')) As
 foo(geom);

 geomewkt
-----+-----
POLYGON((0 0 0,0 1 0,1 1 0,1 0 0,0 0 0))

```

### See Also

## 8.5.30 ST\_PointN

**ST\_PointN** — Return the Nth point in the first LineString or circular LineString in the geometry. Negative values are counted backwards from the end of the LineString. Returns NULL if there is no linestring in the geometry.

### Synopsis

geometry **ST\_PointN**(geometry a\_linestring, integer n);

### Description

Return the Nth point in a single linestring or circular linestring in the geometry. Negative values are counted backwards from the end of the LineString, so that -1 is the last point. Returns NULL if there is no linestring in the geometry.

#### Note

Index is 1-based as for OGC specs since version 0.8.0. Backward indexing (negative index) is not in OGC Previous versions implemented this as 0-based instead.

#### Note

If you want to get the nth point of each line string in a multilinestring, use in conjunction with [ST\\_Dump](#)

This method implements the [OpenGIS Simple Features Implementation Specification for SQL 1.1](#).

This method implements the SQL/MM specification. SQL-MM 3: 7.2.5, 7.3.5

This function supports 3d and will not drop the z-index.

This method supports Circular Strings and Curves

**Note**

Changed: 2.0.0 no longer works with single geometry multilinestrings. In older versions of PostGIS -- a single line multilinestring would work happily with this function and return the start point. In 2.0.0 it just returns NULL like any other multilinestring.

Changed: 2.3.0 : negative indexing available (-1 is last point)

**Examples**

```
-- Extract all POINTs from a LINESTRING
SELECT ST_AsText(
 ST_PointN(
 column1,
 generate_series(1, ST_NPoints(column1))
)
)
FROM (VALUES ('LINESTRING(0 0, 1 1, 2 2)::geometry')) AS foo;

st_astext

POINT(0 0)
POINT(1 1)
POINT(2 2)
(3 rows)

--Example circular string
SELECT ST_AsText(ST_PointN(ST_GeomFromText('CIRCULARSTRING(1 2, 3 2, 1 2)'),2));

st_astext

POINT(3 2)

SELECT st_astext(f)
FROM ST_GeometryFromtext('LINESTRING(0 0 0, 1 1 1, 2 2 2)') as g
,ST_PointN(g, -2) AS f -- 1 based index

st_astext

"POINT Z (1 1 1)"
```

**See Also**

[ST\\_NPoints](#)

**8.5.31 ST\_Points**

**ST\_Points** — Returns a MultiPoint containing all of the coordinates of a geometry.

**Synopsis**

```
geometry ST_Points(geometry geom);
```

## Description

Returns a MultiPoint containing all of the coordinates of a geometry. Does not remove points that are duplicated in the input geometry, including start and end points of ring geometries. (If this behavior is undesired, duplicates may be removed using [ST\\_RemoveRepeatedPoints](#)).

M and Z ordinates will be preserved if present.

This method supports Circular Strings and Curves

This function supports 3d and will not drop the z-index.

Availability: 2.3.0

## Examples

```
SELECT ST_AsText(ST_Points('POLYGON Z ((30 10 4,10 30 5,40 40 6, 30 10))'));

--result
MULTIPOINT Z (30 10 4,10 30 5,40 40 6, 30 10 4)
```

## See Also

[ST\\_RemoveRepeatedPoints](#)

## 8.5.32 ST\_SRID

ST\_SRID — Returns the spatial reference identifier for the ST\_Geometry as defined in spatial\_ref\_sys table.

## Synopsis

integer **ST\_SRID**(geometry g1);

## Description

Returns the spatial reference identifier for the ST\_Geometry as defined in spatial\_ref\_sys table. Section [4.3.1](#)

### Note

spatial\_ref\_sys table is a table that catalogs all spatial reference systems known to PostGIS and is used for transformations from one spatial reference system to another. So verifying you have the right spatial reference system identifier is important if you plan to ever transform your geometries.

This method implements the [OpenGIS Simple Features Implementation Specification for SQL 1.1](#). s2.1.1.1

This method implements the SQL/MM specification. SQL-MM 3: 5.1.5

This method supports Circular Strings and Curves

## Examples

```
SELECT ST_SRID(ST_GeomFromText('POINT(-71.1043 42.315)',4326));
--result
4326
```

## See Also

Section [4.3.1](#), [ST\\_GeomFromText](#), [ST\\_SetSRID](#), [ST\\_Transform](#)

### 8.5.33 ST\_StartPoint

`ST_StartPoint` — Returns the first point of a `LINestring` geometry as a `POINT`.

#### Synopsis

geometry `ST_StartPoint`(geometry geomA);

#### Description

Returns the first point of a `LINestring` or `CIRCULARLINestring` geometry as a `POINT` or `NULL` if the input parameter is not a `LINestring` or `CIRCULARLINestring`.

This method implements the SQL/MM specification. SQL-MM 3: 7.1.3

This function supports 3d and will not drop the z-index.

This method supports Circular Strings and Curves

#### Note

Changed: 2.0.0 no longer works with single geometry multilinestrings. In older versions of PostGIS -- a single line multilinestring would work happily with this function and return the start point. In 2.0.0 it just returns `NULL` like any other multilinestring. The older behavior was an undocumented feature, but people who assumed they had their data stored as `LINestring` may experience these returning `NULL` in 2.0 now.

## Examples

```
SELECT ST_AsText(ST_StartPoint('LINestring(0 1, 0 2)::geometry'));
st_astext

POINT(0 1)
(1 row)

SELECT ST_StartPoint('POINT(0 1)::geometry') IS NULL AS is_null;
is_null

t
(1 row)

--3d line
SELECT ST_AsEWKT(ST_StartPoint('LINestring(0 1 1, 0 2 2)::geometry'));
```

```

st_asewkt

POINT(0 1 1)
(1 row)

-- circular linestring --
SELECT ST_AsText(ST_StartPoint('CIRCULARSTRING(5 2,-3 1.999999, -2 1, -4 2, 5 2)')::geometry ←
));
st_astext

POINT(5 2)

```

**See Also**

[ST\\_EndPoint](#), [ST\\_PointN](#)

**8.5.34 ST\_Summary**

`ST_Summary` — Returns a text summary of the contents of the geometry.

**Synopsis**

```

text ST_Summary(geometry g);
text ST_Summary(geography g);

```

**Description**

Returns a text summary of the contents of the geometry.

Flags shown square brackets after the geometry type have the following meaning:

- **M**: has M ordinate
- **Z**: has Z ordinate
- **B**: has a cached bounding box
- **G**: is geodetic (geography)
- **S**: has spatial reference system

This method supports Circular Strings and Curves

This function supports Polyhedral surfaces.

This function supports Triangles and Triangulated Irregular Network Surfaces (TIN).

Availability: 1.2.2

Enhanced: 2.0.0 added support for geography

Enhanced: 2.1.0 S flag to denote if has a known spatial reference system

Enhanced: 2.2.0 Added support for TIN and Curves

## Examples

```

=# SELECT ST_Summary(ST_GeomFromText('LINESTRING(0 0, 1 1)')) as geom,
 ST_Summary(ST_GeogFromText('POLYGON((0 0, 1 1, 1 2, 1 1, 0 0))')) geog;
-----+-----
LineString[B] with 2 points | Polygon[BGS] with 1 rings
 | ring 0 has 5 points
 :
(1 row)

=# SELECT ST_Summary(ST_GeogFromText('LINESTRING(0 0 1, 1 1 1)')) As geog_line,
 ST_Summary(ST_GeomFromText('SRID=4326;POLYGON((0 0 1, 1 1 2, 1 2 3, 1 1 1, 0 0 1)) ←
 ') As geom_poly;
;
-----+-----
LineString[ZBGS] with 2 points | Polygon[ZBS] with 1 rings
 : ring 0 has 5 points
 :
(1 row)

```

## 8.5.35 ST\_X

**ST\_X** — Return the X coordinate of the point, or NULL if not available. Input must be a point.

### Synopsis

```
float ST_X(geometry a_point);
```

### Description

Return the X coordinate of the point, or NULL if not available. Input must be a point.

#### Note

If you want to get the max min x values of any geometry look at [ST\\_XMin](#), [ST\\_XMax](#) functions.

This method implements the SQL/MM specification. SQL-MM 3: 6.1.3

This function supports 3d and will not drop the z-index.

## Examples

```
SELECT ST_X(ST_GeomFromEWKT('POINT(1 2 3 4)'));
st_x

1
(1 row)

SELECT ST_Y(ST_Centroid(ST_GeomFromEWKT('LINESTRING(1 2 3 4, 1 1 1 1)')));
st_y

1.5
(1 row)
```

### 8.5.36 ST\_XMax

**ST\_XMax** — Returns X maxima of a bounding box 2d or 3d or a geometry.

#### Synopsis

```
float ST_XMax(box3d aGeomorBox2DorBox3D);
```

#### Description

Returns X maxima of a bounding box 2d or 3d or a geometry.

#### Note

Although this function is only defined for box3d, it will work for box2d and geometry because of the auto-casting behavior defined for geometries and box2d. However you can not feed it a geometry or box2d text representation, since that will not auto-cast.

This function supports 3d and will not drop the z-index.

This method supports Circular Strings and Curves

## Examples

```
SELECT ST_XMax('BOX3D(1 2 3, 4 5 6)');
st_xmax

4

SELECT ST_XMax(ST_GeomFromText('LINESTRING(1 3 4, 5 6 7)'));
st_xmax

5
```

```

SELECT ST_XMax(CAST('BOX(-3 2, 3 4)' As box2d));
st_xmax

3
--Observe THIS DOES NOT WORK because it will try to autocast the string representation to a ←
BOX3D
SELECT ST_XMax('LINESTRING(1 3, 5 6)');

--ERROR: BOX3D parser - doesn't start with BOX3D(

SELECT ST_XMax(ST_GeomFromEWKT('CIRCULARSTRING(220268 150415 1,220227 150505 2,220227 ←
150406 3)'));
st_xmax

220288.248780547

```

**8.5.37 ST\_XMin**

**ST\_XMin** — Returns X minima of a bounding box 2d or 3d or a geometry.

**Synopsis**

```
float ST_XMin(box3d aGeomorBox2DorBox3D);
```

**Description**

Returns X minima of a bounding box 2d or 3d or a geometry.

**Note**

Although this function is only defined for box3d, it will work for box2d and geometry because of the auto-casting behavior defined for geometries and box2d. However you can not feed it a geometry or box2d text representation, since that will not auto-cast.

This function supports 3d and will not drop the z-index.

This method supports Circular Strings and Curves

**Examples**

```

SELECT ST_XMin('BOX3D(1 2 3, 4 5 6)');
st_xmin

1

SELECT ST_XMin(ST_GeomFromText('LINESTRING(1 3 4, 5 6 7)'));
st_xmin

```

```

1

SELECT ST_XMin(CAST('BOX(-3 2, 3 4)' As box2d));
st_xmin

-3
--Observe THIS DOES NOT WORK because it will try to autocast the string representation to a ←
BOX3D
SELECT ST_XMin('LINESTRING(1 3, 5 6)');

--ERROR: BOX3D parser - doesn't start with BOX3D(

SELECT ST_XMin(ST_GeomFromEWKT('CIRCULARSTRING(220268 150415 1,220227 150505 2,220227 ←
150406 3)'));
st_xmin

220186.995121892

```

**8.5.38 ST\_Y**

**ST\_Y** — Return the Y coordinate of the point, or NULL if not available. Input must be a point.

**Synopsis**

```
float ST_Y(geometry a_point);
```

**Description**

Return the Y coordinate of the point, or NULL if not available. Input must be a point.

This method implements the [OpenGIS Simple Features Implementation Specification for SQL 1.1](#).

This method implements the SQL/MM specification. SQL-MM 3: 6.1.4

This function supports 3d and will not drop the z-index.

**Examples**

```

SELECT ST_Y(ST_GeomFromEWKT('POINT(1 2 3 4)'));
st_y

2
(1 row)

SELECT ST_Y(ST_Centroid(ST_GeomFromEWKT('LINESTRING(1 2 3 4, 1 1 1 1)')));
st_y

## 8.5.39 ST\_YMax

ST\_YMax — Returns Y maxima of a bounding box 2d or 3d or a geometry.

### Synopsis

```
float ST_YMax(box3d aGeomorBox2DorBox3D);
```

### Description

Returns Y maxima of a bounding box 2d or 3d or a geometry.

#### Note

Although this function is only defined for box3d, it will work for box2d and geometry because of the auto-casting behavior defined for geometries and box2d. However you can not feed it a geometry or box2d text representation, since that will not auto-cast.

This function supports 3d and will not drop the z-index.

This method supports Circular Strings and Curves

### Examples

```
SELECT ST_YMax('BOX3D(1 2 3, 4 5 6)');
st_ymax

5

SELECT ST_YMax(ST_GeomFromText('LINESTRING(1 3 4, 5 6 7)'));
st_ymax

6

SELECT ST_YMax(CAST('BOX(-3 2, 3 4)' As box2d));
st_ymax

4
--Observe THIS DOES NOT WORK because it will try to autocast the string representation to a ←
BOX3D
SELECT ST_YMax('LINESTRING(1 3, 5 6)');
--ERROR: BOX3D parser - doesn't start with BOX3D(
```

```
SELECT ST_YMax(ST_GeomFromEWKT('CIRCULARSTRING(220268 150415 1,220227 150505 2,220227 150406 3)'));
st_ymax

150506.126829327
```

## 8.5.41 ST\_Z

**ST\_Z** — Return the Z coordinate of the point, or NULL if not available. Input must be a point.

### Synopsis

```
float ST_Z(geometry a_point);
```

### Description

Return the Z coordinate of the point, or NULL if not available. Input must be a point.

This method implements the SQL/MM specification.

This function supports 3d and will not drop the z-index.

### Examples

```
SELECT ST_Z(ST_GeomFromEWKT('POINT(1 2 3 4)'));
st_z

3
(1 row)
```

### See Also

## 8.5.42 ST\_ZMax

**ST\_ZMax** — Returns Z minima of a bounding box 2d or 3d or a geometry.

### Synopsis

```
float ST_ZMax(box3d aGeomorBox2DorBox3D);
```

## Description

Returns Z maxima of a bounding box 2d or 3d or a geometry.

### Note

Although this function is only defined for box3d, it will work for box2d and geometry because of the auto-casting behavior defined for geometries and box2d. However you can not feed it a geometry or box2d text representation, since that will not auto-cast.

This function supports 3d and will not drop the z-index.

This method supports Circular Strings and Curves

## Examples

```
SELECT ST_ZMax('BOX3D(1 2 3, 4 5 6)');
st_zmax

6

SELECT ST_ZMax(ST_GeomFromEWKT('LINESTRING(1 3 4, 5 6 7)'));
st_zmax

7

SELECT ST_ZMax('BOX3D(-3 2 1, 3 4 1)');
st_zmax

### 8.5.43 ST\_Zmflag

**ST\_Zmflag** — Returns ZM (dimension semantic) flag of the geometries as a small int. Values are: 0=2d, 1=3dm, 2=3dz, 3=4d.

## Synopsis

```
smallint ST_Zmflag(geometry geomA);
```

**Description**

Returns ZM (dimension semantic) flag of the geometries as a small int. Values are: 0=2d, 1=3dm, 2=3dz, 3=4d.

This function supports 3d and will not drop the z-index.

This method supports Circular Strings and Curves

**Examples**

```
SELECT ST_Zmflag(ST_GeomFromEWKT('LINESTRING(1 2, 3 4)'));
 st_zmflag

 0

SELECT ST_Zmflag(ST_GeomFromEWKT('LINESTRINGM(1 2 3, 3 4 3)'));
 st_zmflag

 1

SELECT ST_Zmflag(ST_GeomFromEWKT('CIRCULARSTRING(1 2 3, 3 4 3, 5 6 3)'));
 st_zmflag

 2

SELECT ST_Zmflag(ST_GeomFromEWKT('POINT(1 2 3 4)'));
 st_zmflag

 3
```

**8.5.44 ST\_ZMin**

ST\_ZMin — Returns Z minima of a bounding box 2d or 3d or a geometry.

**Synopsis**

```
float ST_ZMin(box3d aGeomorBox2DorBox3D);
```

**Description**

Returns Z minima of a bounding box 2d or 3d or a geometry.

**Note**

Although this function is only defined for box3d, it will work for box2d and geometry because of the auto-casting behavior defined for geometries and box2d. However you can not feed it a geometry or box2d text representation, since that will not auto-cast.

This function supports 3d and will not drop the z-index.

This method supports Circular Strings and Curves

## Examples

```

SELECT ST_ZMin('BOX3D(1 2 3, 4 5 6)');
st_zmin

3

SELECT ST_ZMin(ST_GeomFromEWKT('LINESTRING(1 3 4, 5 6 7)'));
st_zmin

4

SELECT ST_ZMin('BOX3D(-3 2 1, 3 4 1) ');
st_zmin

1
--Observe THIS DOES NOT WORK because it will try to autocast the string representation to a ↵
BOX3D
SELECT ST_ZMin('LINESTRING(1 3 4, 5 6 7)');

--ERROR: BOX3D parser - doesn't start with BOX3D(

SELECT ST_ZMin(ST_GeomFromEWKT('CIRCULARSTRING(220268 150415 1,220227 150505 2,220227 ↵
150406 3)'));
st_zmin

1

```

## 8.6 Geometry Editors

### 8.6.1 ST\_AddPoint

`ST_AddPoint` — Add a point to a `LineString`.

#### Synopsis

```

geometry ST_AddPoint(geometry linestring, geometry point);
geometry ST_AddPoint(geometry linestring, geometry point, integer position);

```

#### Description

Adds a point to a `LineString` before point <position> (0-based index). Third parameter can be omitted or set to -1 for appending.  
 Availability: 1.1.0

This function supports 3d and will not drop the z-index.

## Examples

```
--guarantee all linestrings in a table are closed
--by adding the start point of each linestring to the end of the line string
--only for those that are not closed
UPDATE sometable
SET the_geom = ST_AddPoint(the_geom, ST_StartPoint(the_geom))
FROM sometable
WHERE ST_IsClosed(the_geom) = false;

--Adding point to a 3-d line
SELECT ST_AsEWKT(ST_AddPoint(ST_GeomFromEWKT('LINESTRING(0 0 1, 1 1 1)'), ST_MakePoint ←
 (1, 2, 3)));

--result
st_asewkt

LINESTRING(0 0 1,1 1 1,1 2 3)
```

## See Also

[ST\\_RemovePoint](#), [ST\\_SetPoint](#)

## 8.6.2 ST\_Affine

**ST\_Affine** — Apply a 3d affine transformation to a geometry.

### Synopsis

geometry **ST\_Affine**(geometry geomA, float a, float b, float c, float d, float e, float f, float g, float h, float i, float xoff, float yoff, float zoff);  
 geometry **ST\_Affine**(geometry geomA, float a, float b, float d, float e, float xoff, float yoff);

### Description

Applies a 3d affine transformation to the geometry to do things like translate, rotate, scale in one step.

Version 1: The call

```
ST_Affine(geom, a, b, c, d, e, f, g, h, i, xoff, yoff, zoff)
```

represents the transformation matrix

```
/ a b c xoff \
| d e f yoff |
| g h i zoff |
\ 0 0 0 1 /
```

and the vertices are transformed as follows:

```
x' = a*x + b*y + c*z + xoff
y' = d*x + e*y + f*z + yoff
z' = g*x + h*y + i*z + zoff
```

All of the translate / scale functions below are expressed via such an affine transformation.

Version 2: Applies a 2d affine transformation to the geometry. The call

```
ST_Affine(geom, a, b, d, e, xoff, yoff)
```

represents the transformation matrix

```

/ a b 0 xoff \ / a b xoff \
| d e 0 yoff | rsp. | d e yoff |
| 0 0 1 0 | \ 0 0 1 /
\ 0 0 0 1 /

```

and the vertices are transformed as follows:

```

x' = a*x + b*y + xoff
y' = d*x + e*y + yoff
z' = z

```

This method is a subcase of the 3D method above.

Enhanced: 2.0.0 support for Polyhedral surfaces, Triangles and TIN was introduced.

Availability: 1.1.2. Name changed from Affine to ST\_Affine in 1.2.2

#### Note

Prior to 1.3.4, this function crashes if used with geometries that contain CURVES. This is fixed in 1.3.4+

This function supports Polyhedral surfaces.

This function supports Triangles and Triangulated Irregular Network Surfaces (TIN).

This function supports 3d and will not drop the z-index.

This method supports Circular Strings and Curves

#### Examples

```

--Rotate a 3d line 180 degrees about the z axis. Note this is long-hand for doing ↔
 ST_Rotate();
SELECT ST_AsEWKT(ST_Affine(the_geom, cos(pi()), -sin(pi()), 0, sin(pi()), cos(pi()), 0, ↔
 0, 0, 1, 0, 0, 0)) As using_affine,
 ST_AsEWKT(ST_Rotate(the_geom, pi())) As using_rotate
FROM (SELECT ST_GeomFromEWKT('LINESTRING(1 2 3, 1 4 3)') As the_geom) As foo;
 using_affine | using_rotate
-----+-----
LINESTRING(-1 -2 3,-1 -4 3) | LINESTRING(-1 -2 3,-1 -4 3)
(1 row)

--Rotate a 3d line 180 degrees in both the x and z axis
SELECT ST_AsEWKT(ST_Affine(the_geom, cos(pi()), -sin(pi()), 0, sin(pi()), cos(pi()), -sin(↔
 pi()), 0, sin(pi()), cos(pi()), 0, 0, 0))
FROM (SELECT ST_GeomFromEWKT('LINESTRING(1 2 3, 1 4 3)') As the_geom) As foo;
 st_asewkt

LINESTRING(-1 -2 -3,-1 -4 -3)
(1 row)

```

**8.6.3 ST\_Force2D**

ST\_Force2D — Force the geometries into a "2-dimensional mode".

**Synopsis**

```
geometry ST_Force2D(geometry geomA);
```

**Description**

Forces the geometries into a "2-dimensional mode" so that all output representations will only have the X and Y coordinates. This is useful for force OGC-compliant output (since OGC only specifies 2-D geometries).

Enhanced: 2.0.0 support for Polyhedral surfaces was introduced.

Changed: 2.1.0. Up to 2.0.x this was called ST\_Force\_2D.

This method supports Circular Strings and Curves

This function supports Polyhedral surfaces.

This function supports 3d and will not drop the z-index.

**Examples**

```
SELECT ST_AsEWKT(ST_Force2D(ST_GeomFromEWKT('CIRCULARSTRING(1 1 2, 2 3 2, 4 5 2, 6 7 2, 5 6 ←
2)')));
 st_asewkt

CIRCULARSTRING(1 1,2 3,4 5,6 7,5 6)

SELECT ST_AsEWKT(ST_Force2D('POLYGON((0 0 2,0 5 2,5 0 2,0 0 2),(1 1 2,3 1 2,1 3 2,1 1 2)) ←
'));
 st_asewkt

POLYGON((0 0,0 5,5 0,0 0),(1 1,3 1,1 3,1 1))
```

**See Also**

[ST\\_Force3D](#)

**8.6.4 ST\_Force3D**

ST\_Force3D — Force the geometries into XYZ mode. This is an alias for ST\_Force3DZ.

**Synopsis**

geometry **ST\_Force3D**(geometry geomA);

**Description**

Forces the geometries into XYZ mode. This is an alias for `ST_Force_3DZ`. If a geometry has no Z component, then a 0 Z coordinate is tacked on.

Enhanced: 2.0.0 support for Polyhedral surfaces was introduced.

Changed: 2.1.0. Up to 2.0.x this was called `ST_Force_3D`.

This function supports Polyhedral surfaces.

This method supports Circular Strings and Curves

This function supports 3d and will not drop the z-index.

**Examples**

```
--Nothing happens to an already 3D geometry
SELECT ST_AsEWKT(ST_Force3D(ST_GeomFromEWKT('CIRCULARSTRING(1 1 2, 2 3 2, 4 5 2, 6 7 2, ↵
 5 6 2)')));
 st_asewkt

CIRCULARSTRING(1 1 2,2 3 2,4 5 2,6 7 2,5 6 2)

SELECT ST_AsEWKT(ST_Force3D('POLYGON((0 0,0 5,5 0,0 0),(1 1,3 1,1 3,1 1))'));
 st_asewkt

POLYGON((0 0 0,0 5 0,5 0 0,0 0 0),(1 1 0,3 1 0,1 3 0,1 1 0))
```

**8.6.5 ST\_Force3DZ**

`ST_Force3DZ` — Force the geometries into XYZ mode.

**Synopsis**

geometry **ST\_Force3DZ**(geometry geomA);

## Description

Forces the geometries into XYZ mode. This is a synonym for `ST_Force3DZ`. If a geometry has no Z component, then a 0 Z coordinate is tacked on.

Enhanced: 2.0.0 support for Polyhedral surfaces was introduced.

Changed: 2.1.0. Up to 2.0.x this was called `ST_Force_3DZ`.

This function supports Polyhedral surfaces.

This function supports 3d and will not drop the z-index.

This method supports Circular Strings and Curves

## Examples

```
--Nothing happens to an already 3D geometry
SELECT ST_AsEWKT(ST_Force3DZ(ST_GeomFromEWKT('CIRCULARSTRING(1 1 2, 2 3 2, 4 5 2, 6 7 2, 5 6 2)')));
 st_asewkt

CIRCULARSTRING(1 1 2,2 3 2,4 5 2,6 7 2,5 6 2)

SELECT ST_AsEWKT(ST_Force3DZ('POLYGON((0 0,0 5,5 0,0 0),(1 1,3 1,1 3,1 1))'));
 st_asewkt

POLYGON((0 0 0,0 5 0,5 0 0,0 0 0),(1 1 0,3 1 0,1 3 0,1 1 0))
```

### 8.6.6 ST\_Force3DM

`ST_Force3DM` — Force the geometries into XYM mode.

#### Synopsis

```
geometry ST_Force3DM(geometry geomA);
```

#### Description

Forces the geometries into XYM mode. If a geometry has no M component, then a 0 M coordinate is tacked on. If it has a Z component, then Z is removed

Changed: 2.1.0. Up to 2.0.x this was called `ST_Force_3DM`.

This method supports Circular Strings and Curves

## Examples

```
--Nothing happens to an already 3D geometry
SELECT ST_AsEWKT(ST_Force3DM(ST_GeomFromEWKT('CIRCULARSTRING(1 1 2, 2 3 2, 4 5 2, 6 7 2, 5 6 2)')));
 st_asewkt

CIRCULARSTRINGM(1 1 0,2 3 0,4 5 0,6 7 0,5 6 0)

SELECT ST_AsEWKT(ST_Force3DM('POLYGON((0 0 1,0 5 1,5 0 1,0 0 1),(1 1 1,3 1 1,1 3 1,1 1 1))'));
 st_asewkt

POLYGONM((0 0 0,0 5 0,5 0 0,0 0 0),(1 1 0,3 1 0,1 3 0,1 1 0))
```

## 8.6.7 ST\_Force4D

ST\_Force4D — Force the geometries into XYZM mode.

### Synopsis

geometry **ST\_Force4D**(geometry geomA);

### Description

Forces the geometries into XYZM mode. 0 is tacked on for missing Z and M dimensions.

Changed: 2.1.0. Up to 2.0.x this was called ST\_Force\_4D.

This function supports 3d and will not drop the z-index.

This method supports Circular Strings and Curves

## Examples

```
--Nothing happens to an already 3D geometry
SELECT ST_AsEWKT(ST_Force4D(ST_GeomFromEWKT('CIRCULARSTRING(1 1 2, 2 3 2, 4 5 2, 6 7 2, 5 6 2)')));
 st_asewkt

CIRCULARSTRING(1 1 2 0,2 3 2 0,4 5 2 0,6 7 2 0,5 6 2 0)

SELECT ST_AsEWKT(ST_Force4D('MULTILINESTRINGM((0 0 1,0 5 2,5 0 3,0 0 4),(1 1 1,3 1 1,1 3 1,1 1 1))'));
 st_asewkt

MULTILINESTRINGM((0 0 0,0 5 0,5 0 0,0 0 0),(1 1 0,3 1 0,1 3 0,1 1 0))
```

```
st_asewkt
```

```
MULTILINESTRING((0 0 0 1,0 5 0 2,5 0 0 3,0 0 0 4),(1 1 0 1,3 1 0 1,1 3 0 1,1 1 0 1))
```

## 8.6.8 ST\_ForceCollection

`ST_ForceCollection` — Convert the geometry into a `GEOMETRYCOLLECTION`.

### Synopsis

```
geometry ST_ForceCollection(geometry geomA);
```

### Description

Converts the geometry into a `GEOMETRYCOLLECTION`. This is useful for simplifying the WKB representation.

Enhanced: 2.0.0 support for Polyhedral surfaces was introduced.

Availability: 1.2.2, prior to 1.3.4 this function will crash with Curves. This is fixed in 1.3.4+

Changed: 2.1.0. Up to 2.0.x this was called `ST_Force_Collection`.

This function supports Polyhedral surfaces.

This function supports 3d and will not drop the z-index.

This method supports Circular Strings and Curves

### Examples

```
SELECT ST_AsEWKT(ST_ForceCollection('POLYGON((0 0 1,0 5 1,5 0 1,0 0 1),(1 1 1,3 1 1,1 3 1,1 1 1))'));
```

```
st_asewkt
```

```
GEOMETRYCOLLECTION(POLYGON((0 0 1,0 5 1,5 0 1,0 0 1),(1 1 1,3 1 1,1 3 1,1 1 1))
```

```
SELECT ST_AsText(ST_ForceCollection('CIRCULARSTRING(220227 150406,220227 150407,220227 150406)'));
```

```
st_astext
```

```
GEOMETRYCOLLECTION(CIRCULARSTRING(220227 150406,220227 150407,220227 150406))
(1 row)
```

```

-- POLYHEDRAL example --
SELECT ST_AsEWKT(ST_ForceCollection('POLYHEDRALSURFACE(((0 0 0,0 0 1,0 1 1,0 1 0,0 0 0)),

**8.6.9 ST\_ForceSFS**

`ST_ForceSFS` — Force the geometries to use SFS 1.1 geometry types only.

**Synopsis**

```

geometry ST_ForceSFS(geometry geomA);
geometry ST_ForceSFS(geometry geomA, text version);

```

**Description**

This function supports Polyhedral surfaces.

This function supports Triangles and Triangulated Irregular Network Surfaces (TIN).

This method supports Circular Strings and Curves

This function supports 3d and will not drop the z-index.

**8.6.10 ST\_ForceRHR**

`ST_ForceRHR` — Force the orientation of the vertices in a polygon to follow the Right-Hand-Rule.

**Synopsis**

```

geometry ST_ForceRHR(geometry g);

```

## Description

Forces the orientation of the vertices in a polygon to follow the Right-Hand-Rule. In GIS terminology, this means that the area that is bounded by the polygon is to the right of the boundary. In particular, the exterior ring is orientated in a clockwise direction and the interior rings in a counter-clockwise direction.

Enhanced: 2.0.0 support for Polyhedral surfaces was introduced.

This function supports 3d and will not drop the z-index.

This function supports Polyhedral surfaces.

## Examples

```
SELECT ST_AsEWKT(
 ST_ForceRHR(
 'POLYGON((0 0 2, 5 0 2, 0 5 2, 0 0 2),(1 1 2, 1 3 2, 3 1 2, 1 1 2))'
)
);
 st_asewkt

POLYGON((0 0 2,0 5 2,5 0 2,0 0 2),(1 1 2,3 1 2,1 3 2,1 1 2))
(1 row)
```

## See Also

### 8.6.11 ST\_ForceCurve

`ST_ForceCurve` — Upcast a geometry into its curved type, if applicable.

#### Synopsis

geometry `ST_ForceCurve`(geometry g);

#### Description

Turns a geometry into its curved representation, if applicable: lines become compoundcurves, multilines become multicurves polygons become curvepolygons multipolygons become multisurfaces. If the geometry input is already a curved representation returns back same as input.

Availability: 2.2.0

This function supports 3d and will not drop the z-index.

This method supports Circular Strings and Curves

## Examples

```
SELECT ST_AsText(
 ST_ForceCurve(
 'POLYGON((0 0 2, 5 0 2, 0 5 2, 0 0 2),(1 1 2, 1 3 2, 3 1 2, 1 1 2))'::geometry
)
);
 st_astext

CURVEPOLYGON Z ((0 0 2,5 0 2,0 5 2,0 0 2),(1 1 2,1 3 2,3 1 2,1 1 2))
(1 row)
```

## See Also

### 8.6.12 ST\_LineMerge

`ST_LineMerge` — Return a (set of) `LineString`(s) formed by sewing together a `MULTILINESTRING`.

#### Synopsis

geometry `ST_LineMerge`(geometry amultilinestring);

#### Description

Returns a (set of) `LineString`(s) formed by sewing together the constituent line work of a `MULTILINESTRING`.

#### Note

Only use with `MULTILINESTRING/LINESTRING`s. If you feed a polygon or geometry collection into this function, it will return an empty `GEOMETRYCOLLECTION`

Availability: 1.1.0

#### Note

requires GEOS >= 2.1.0

## Examples

```
SELECT ST_AsText(ST_LineMerge(
 ST_GeomFromText('MULTILINESTRING((-29 -27,-30 -29.7,-36 -31,-45 -33),(-45 -33,-46 -32))')
)
);
 st_astext

LINESTRING(-29 -27,-30 -29.7,-36 -31,-45 -33,-46 -32)
(1 row)
```

```
--If can't be merged - original MULTILINESTRING is returned
SELECT ST_AsText(ST_LineMerge(
ST_GeomFromText('MULTILINESTRING((-29 -27,-30 -29.7,-36 -31,-45 -33), (-45.2 -33.2,-46 -32))' ←
)
);
st_astext

MULTILINESTRING((-45.2 -33.2,-46 -32), (-29 -27,-30 -29.7,-36 -31,-45 -33))
```

### 8.6.13 ST\_CollectionExtract

**ST\_CollectionExtract** — Given a (multi)geometry, return a (multi)geometry consisting only of elements of the specified type.

#### Synopsis

geometry **ST\_CollectionExtract**(geometry collection, integer type);

#### Description

Given a (multi)geometry, returns a (multi)geometry consisting only of elements of the specified type. Sub-geometries that are not the specified type are ignored. If there are no sub-geometries of the right type, an EMPTY geometry will be returned. Only points, lines and polygons are supported. Type numbers are 1 == POINT, 2 == LINESTRING, 3 == POLYGON.

Availability: 1.5.0

#### Note

Prior to 1.5.3 this function returned non-collection inputs untouched, no matter type. In 1.5.3 non-matching single geometries result in a NULL return. In of 2.0.0 every case of missing match results in a typed EMPTY return.

#### Warning

When specifying 3 == POLYGON a multipolygon is returned even when the edges are shared. This results in an invalid multipolygon for many cases such as applying this function on an [ST\\_Split](#) result.

#### Examples

```
-- Constants: 1 == POINT, 2 == LINESTRING, 3 == POLYGON
SELECT ST_AsText(ST_CollectionExtract(ST_GeomFromText('GEOMETRYCOLLECTION(←
GEOMETRYCOLLECTION(POINT(0 0))'),1));
st_astext

MULTIPOINT(0 0)
(1 row)

SELECT ST_AsText(ST_CollectionExtract(ST_GeomFromText('GEOMETRYCOLLECTION(←
GEOMETRYCOLLECTION(LINESTRING(0 0, 1 1),LINESTRING(2 2, 3 3))'),2));
```

```

st_astext

MULTILINESTRING((0 0, 1 1), (2 2, 3 3))
(1 row)

```

**8.6.14 ST\_CollectionHomogenize**

`ST_CollectionHomogenize` — Given a geometry collection, return the "simplest" representation of the contents.

**Synopsis**

```
geometry ST_CollectionHomogenize(geometry collection);
```

**Description**

Given a geometry collection, returns the "simplest" representation of the contents. Singletons will be returned as singletons. Collections that are homogeneous will be returned as the appropriate multi-type.

**Warning**

When specifying `3 == POLYGON` a multipolygon is returned even when the edges are shared. This results in an invalid multipolygon for many cases such as applying this function on an [ST\\_Split](#) result.

Availability: 2.0.0

**Examples**

```

SELECT ST_AsText(ST_CollectionHomogenize('GEOMETRYCOLLECTION(POINT(0 0))'));

st_astext

POINT(0 0)
(1 row)

SELECT ST_AsText(ST_CollectionHomogenize('GEOMETRYCOLLECTION(POINT(0 0),POINT(1 1))'));

st_astext

MULTIPOINT(0 0,1 1)
(1 row)

```

### 8.6.15 ST\_Multi

`ST_Multi` — Return the geometry as a MULTI\* geometry.

#### Synopsis

```
geometry ST_Multi(geometry g1);
```

#### Description

Returns the geometry as a MULTI\* geometry. If the geometry is already a MULTI\*, it is returned unchanged.

#### Examples

```
SELECT ST_AsText(ST_Multi(ST_GeomFromText('POLYGON((743238 2967416,743238 2967450,
743265 2967450,743265.625 2967416,743238 2967416))'));
st_astext

MULTIPOLYGON(((743238 2967416,743238 2967450,743265 2967450,743265.625 2967416,
743238 2967416)))
(1 row)
```

### 8.6.16 ST\_Normalize

`ST_Normalize` — Return the geometry in its canonical form.

#### Synopsis

```
geometry ST_Normalize(geometry geom);
```

#### Description

Returns the geometry in its normalized/canonical form. May reorder vertices in polygon rings, rings in a polygon, elements in a multi-geometry complex.

Mostly only useful for testing purposes (comparing expected and obtained results).

#### Examples

```
SELECT ST_AsText(ST_Normalize(ST_GeomFromText (
'GEOMETRYCOLLECTION (
POINT(2 3),
MULTILINESTRING((0 0, 1 1),(2 2, 3 3)),
POLYGON (
(0 10,0 0,10 0,10 10,0 10),
(4 2,2 2,2 4,4 4,4 2),
(6 8,8 8,8 6,6 6,6 8)
)
)
)
)
```

```

)
)'
))) ;
 st_astext

GEOMETRYCOLLECTION(POLYGON((0 0,0 10,10 10,10 0,0 0),(6 6,8 6,8 8,6 8,6 6),(2 2,4 2,4 4,2 4,2 2)),MULTILINESTRING((2 2,3 3),(0 0,1 1)),POINT(2 3))
(1 row)

```

**See Also**[ST\\_Equals](#),**8.6.17 ST\_RemovePoint****ST\_RemovePoint** — Remove point from a linestring.**Synopsis**

```
geometry ST_RemovePoint(geometry linestring, integer offset);
```

**Description**

Remove a point from a linestring, given its 0-based index. Useful for turning a closed ring into an open line string

Availability: 1.1.0

This function supports 3d and will not drop the z-index.

**Examples**

```

--guarantee no LINESTRINGS are closed
--by removing the end point. The below assumes the_geom is of type LINESTRING
UPDATE sometable
 SET the_geom = ST_RemovePoint(the_geom, ST_NPoints(the_geom) - 1)
 FROM sometable
 WHERE ST_IsClosed(the_geom) = true;

```

**See Also**[ST\\_AddPoint](#), [ST\\_NPoints](#), [ST\\_NumPoints](#)**8.6.18 ST\_Reverse****ST\_Reverse** — Return the geometry with vertex order reversed.**Synopsis**

```
geometry ST_Reverse(geometry g1);
```

**Description**

Can be used on any geometry and reverses the order of the vertexes.

**Examples**

```
SELECT ST_AsText(the_geom) as line, ST_AsText(ST_Reverse(the_geom)) As reverseline
FROM
(SELECT ST_MakeLine(ST_MakePoint(1,2),
 ST_MakePoint(1,10)) As the_geom) as foo;
--result
 line | reverseline
-----+-----
LINESTRING(1 2,1 10) | LINESTRING(1 10,1 2)
```

**8.6.19 ST\_Rotate**

**ST\_Rotate** — Rotate a geometry rotRadians counter-clockwise about an origin.

**Synopsis**

```
geometry ST_Rotate(geometry geomA, float rotRadians);
geometry ST_Rotate(geometry geomA, float rotRadians, float x0, float y0);
geometry ST_Rotate(geometry geomA, float rotRadians, geometry pointOrigin);
```

**Description**

Rotates geometry rotRadians counter-clockwise about the origin. The rotation origin can be specified either as a POINT geometry, or as x and y coordinates. If the origin is not specified, the geometry is rotated about POINT(0 0).

Enhanced: 2.0.0 support for Polyhedral surfaces, Triangles and TIN was introduced.

Enhanced: 2.0.0 additional parameters for specifying the origin of rotation were added.

Availability: 1.1.2. Name changed from Rotate to ST\_Rotate in 1.2.2

This function supports 3d and will not drop the z-index.

This method supports Circular Strings and Curves

This function supports Polyhedral surfaces.

This function supports Triangles and Triangulated Irregular Network Surfaces (TIN).

**Examples**

```
--Rotate 180 degrees
SELECT ST_AsEWKT(ST_Rotate('LINESTRING (50 160, 50 50, 100 50)', pi()));
 st_asewkt

LINESTRING(-50 -160,-50 -50,-100 -50)
(1 row)
```

```

--Rotate 30 degrees counter-clockwise at x=50, y=160
SELECT ST_AsEWKT(ST_Rotate('LINESTRING (50 160, 50 50, 100 50)', pi()/6, 50, 160));
 st_asewkt

LINESTRING(50 160,105 64.7372055837117,148.301270189222 89.7372055837117)
(1 row)

--Rotate 60 degrees clockwise from centroid
SELECT ST_AsEWKT(ST_Rotate(geom, -pi()/3, ST_Centroid(geom)))
FROM (SELECT 'LINESTRING (50 160, 50 50, 100 50)::geometry AS geom) AS foo;
 st_asewkt

LINESTRING(116.4225 130.6721,21.1597 75.6721,46.1597 32.3708)
(1 row)

```

**8.6.20 ST\_RotateX**

ST\_RotateX — Rotate a geometry rotRadians about the X axis.

**Synopsis**

geometry **ST\_RotateX**(geometry geomA, float rotRadians);

**Description**

Rotate a geometry geomA - rotRadians about the X axis.

**Note**

ST\_RotateX(geomA, rotRadians) is short-hand for ST\_Affine(geomA, 1, 0, 0, 0, cos(rotRadians), -sin(rotRadians), 0, sin(rotRadians), cos(rotRadians), 0, 0, 0).

Enhanced: 2.0.0 support for Polyhedral surfaces, Triangles and TIN was introduced.

Availability: 1.1.2. Name changed from RotateX to ST\_RotateX in 1.2.2

This function supports Polyhedral surfaces.

This function supports 3d and will not drop the z-index.

This function supports Triangles and Triangulated Irregular Network Surfaces (TIN).

**Examples**

```

--Rotate a line 90 degrees along x-axis
SELECT ST_AsEWKT(ST_RotateX(ST_GeomFromEWKT('LINESTRING(1 2 3, 1 1 1)'), pi()/2));
 st_asewkt

LINESTRING(1 -3 2,1 -1 1)

```

**8.6.21 ST\_RotateY**

ST\_RotateY — Rotate a geometry rotRadians about the Y axis.

**Synopsis**

```
geometry ST_RotateY(geometry geomA, float rotRadians);
```

**Description**

Rotate a geometry geomA - rotRadians about the y axis.

**Note**

ST\_RotateY(geomA, rotRadians) is short-hand for ST\_Affine(geomA, cos(rotRadians), 0, sin(rotRadians), 0, 1, 0, -sin(rotRadians), 0, cos(rotRadians), 0, 0, 0).

Availability: 1.1.2. Name changed from RotateY to ST\_RotateY in 1.2.2

Enhanced: 2.0.0 support for Polyhedral surfaces, Triangles and TIN was introduced.

This function supports Polyhedral surfaces.

This function supports 3d and will not drop the z-index.

This function supports Triangles and Triangulated Irregular Network Surfaces (TIN).

**Examples**

```
--Rotate a line 90 degrees along y-axis
SELECT ST_AsEWKT(ST_RotateY(ST_GeomFromEWKT('LINESTRING(1 2 3, 1 1 1)'), pi()/2));
 st_asewkt

LINESTRING(3 2 -1,1 1 -1)
```

**8.6.22 ST\_RotateZ**

ST\_RotateZ — Rotate a geometry rotRadians about the Z axis.

**Synopsis**

```
geometry ST_RotateZ(geometry geomA, float rotRadians);
```

## Description

Rotate a geometry geomA - rotRadians about the Z axis.

### Note

This is a synonym for ST\_Rotate

### Note

ST\_RotateZ(geomA, rotRadians) is short-hand for SELECT ST\_Affine(geomA, cos(rotRadians), -sin(rotRadians), 0, sin(rotRadians), cos(rotRadians), 0, 0, 0, 1, 0, 0, 0).

Enhanced: 2.0.0 support for Polyhedral surfaces, Triangles and TIN was introduced.

Availability: 1.1.2. Name changed from RotateZ to ST\_RotateZ in 1.2.2

### Note

Prior to 1.3.4, this function crashes if used with geometries that contain CURVES. This is fixed in 1.3.4+

This function supports 3d and will not drop the z-index.

This method supports Circular Strings and Curves

This function supports Polyhedral surfaces.

This function supports Triangles and Triangulated Irregular Network Surfaces (TIN).

## Examples

```
--Rotate a line 90 degrees along z-axis
SELECT ST_AsEWKT(ST_RotateZ(ST_GeomFromEWKT('LINESTRING(1 2 3, 1 1 1)'), pi()/2));
 st_asewkt

LINESTRING(-2 1 3,-1 1 1)

--Rotate a curved circle around z-axis
SELECT ST_AsEWKT(ST_RotateZ(the_geom, pi()/2))
FROM (SELECT ST_LineToCurve(ST_Buffer(ST_GeomFromText('POINT(234 567)'), 3)) As the_geom) ↔
 As foo;
 st_asewkt

CURVEPOLYGON(CIRCULARSTRING(-567 237,-564.87867965644 236.12132034356,-564 ↔
234,-569.12132034356 231.87867965644,-567 237))
```

**See Also**

[ST\\_Affine](#), [ST\\_RotateX](#), [ST\\_RotateY](#)

**8.6.23 ST\_Scale**

`ST_Scale` — Scale a geometry by given factors.

**Synopsis**

```
geometry ST_Scale(geometry geomA, float XFactor, float YFactor, float ZFactor);
geometry ST_Scale(geometry geomA, float XFactor, float YFactor);
geometry ST_Scale(geometry geom, geometry factor);
```

**Description**

Scales the geometry to a new size by multiplying the ordinates with the corresponding factor parameters.

The version taking a geometry as the `factor` parameter allows passing a 2d, 3dm, 3dz or 4d point to set scaling factor for all supported dimensions. Missing dimensions in the `factor` point are equivalent to no scaling the corresponding dimension.

**Note**

Prior to 1.3.4, this function crashes if used with geometries that contain CURVES. This is fixed in 1.3.4+

Availability: 1.1.0.

Enhanced: 2.0.0 support for Polyhedral surfaces, Triangles and TIN was introduced.

Enhanced: 2.2.0 support for scaling all dimension (geometry parameter) was introduced.

This function supports Polyhedral surfaces.

This function supports 3d and will not drop the z-index.

This method supports Circular Strings and Curves

This function supports Triangles and Triangulated Irregular Network Surfaces (TIN).

This function supports M coordinates.

**Examples**

```
--Version 1: scale X, Y, Z
SELECT ST_AsEWKT(ST_Scale(ST_GeomFromEWKT('LINESTRING(1 2 3, 1 1 1)'), 0.5, 0.75, 0.8));
 st_asewkt

LINESTRING(0.5 1.5 2.4,0.5 0.75 0.8)

--Version 2: Scale X Y
SELECT ST_AsEWKT(ST_Scale(ST_GeomFromEWKT('LINESTRING(1 2 3, 1 1 1)'), 0.5, 0.75));
```

```

 st_asewkt

LINESTRING(0.5 1.5 3,0.5 0.75 1)

--Version 3: Scale X Y Z M
SELECT ST_AsEWKT(ST_Scale(ST_GeomFromEWKT('LINESTRING(1 2 3 4, 1 1 1 1)'),
 ST_MakePoint(0.5, 0.75, 2, -1)));
 st_asewkt

LINESTRING(0.5 1.5 6 -4,0.5 0.75 2 -1)

```

**See Also**

[ST\\_Affine](#), [ST\\_TransScale](#)

**8.6.24 ST\_Segmentize**

**ST\_Segmentize** — Return a modified geometry/geography having no segment longer than the given distance.

**Synopsis**

```

geometry ST_Segmentize(geometry geom, float max_segment_length);
geography ST_Segmentize(geography geog, float max_segment_length);

```

**Description**

Returns a modified geometry having no segment longer than the given `max_segment_length`. Distance computation is performed in 2d only. For geometry, length units are in units of spatial reference. For geography, units are in meters.

Availability: 1.2.2

Enhanced: 2.3.0 Segmentize geography now uses equal length segments

Enhanced: 2.1.0 support for geography was introduced.

Changed: 2.1.0 As a result of the introduction of geography support: The construct `SELECT ST_Segmentize('LINESTRING(1 2, 3 4)', 0.5);` will result in ambiguous function error. You need to have properly typed object e.g. a geometry/geography column, use `ST_GeomFromText`, `ST_GeogFromText` or `SELECT ST_Segmentize('LINESTRING(1 2, 3 4)'::geometry, 0.5);`

**Note**

This will only increase segments. It will not lengthen segments shorter than max length

**Examples**

```

SELECT ST_AsText(ST_Segmentize(
ST_GeomFromText('MULTILINESTRING((-29 -27,-30 -29.7,-36 -31,-45 -33), (-45 -33,-46 -32))')
, 5)
);
st_astext

```

```
MULTILINESTRING((-29 -27,-30 -29.7,-34.886615700134 -30.758766735029,-36 -31,
-40.8809353009198 -32.0846522890933,-45 -33),
(-45 -33,-46 -32))
(1 row)

SELECT ST_AsText(ST_Segmentize(ST_GeomFromText('POLYGON((-29 28, -30 40, -29 28)'),10));
st_astext

POLYGON((-29 28,-29.8304547985374 37.9654575824488,-30 40,-29.1695452014626 ↵
30.0345424175512,-29 28))
(1 row)
```

### 8.6.25 ST\_SetPoint

**ST\_SetPoint** — Replace point of a linestring with a given point.

#### Synopsis

geometry **ST\_SetPoint**(geometry linestring, integer zerobasedposition, geometry point);

#### Description

Replace point N of linestring with given point. Index is 0-based. Negative index are counted backwards, so that -1 is last point. This is especially useful in triggers when trying to maintain relationship of joints when one vertex moves.

Availability: 1.1.0

Updated 2.3.0 : negative indexing

This function supports 3d and will not drop the z-index.

#### Examples

```
--Change first point in line string from -1 3 to -1 1
SELECT ST_AsText(ST_SetPoint('LINESTRING(-1 2,-1 3)', 0, 'POINT(-1 1)'));
st_astext

LINESTRING(-1 1,-1 3)

---Change last point in a line string (lets play with 3d linestring this time)
SELECT ST_AsEWKT(ST_SetPoint(foo.the_geom, ST_NumPoints(foo.the_geom) - 1, ST_GeomFromEWKT ↵
('POINT(-1 1 3)'))
FROM (SELECT ST_GeomFromEWKT('LINESTRING(-1 2 3,-1 3 4, 5 6 7)') As the_geom) As foo;
st_asewkt

LINESTRING(-1 2 3,-1 3 4,-1 1 3)

SELECT ST_AsText(ST_SetPoint(g, -3, p))
FROM ST_GeomFromText('LINESTRING(0 0, 1 1, 2 2, 3 3, 4 4)') AS g
, ST_PointN(g,1) as p;
```

```
st_astext

LINESTRING(0 0,1 1,0 0,3 3,4 4)
```

## 8.6.26 ST\_SetSRID

**ST\_SetSRID** — Set the SRID on a geometry to a particular integer value.

### Synopsis

geometry **ST\_SetSRID**(geometry geom, integer srid);

### Description

Sets the SRID on a geometry to a particular integer value. Useful in constructing bounding boxes for queries.

#### Note

This function does not transform the geometry coordinates in any way - it simply sets the meta data defining the spatial reference system the geometry is assumed to be in. Use [ST\\_Transform](#) if you want to transform the geometry into a new projection.

This method implements the [OpenGIS Simple Features Implementation Specification for SQL 1.1](#).

This method supports Circular Strings and Curves

### Examples

-- Mark a point as WGS 84 long lat --

```
SELECT ST_SetSRID(ST_Point(-123.365556, 48.428611),4326) As wgs84long_lat;
-- the ewkt representation (wrap with ST_AsEWKT) -
SRID=4326;POINT(-123.365556 48.428611)
```

-- Mark a point as WGS 84 long lat and then transform to web mercator (Spherical Mercator) --

```
SELECT ST_Transform(ST_SetSRID(ST_Point(-123.365556, 48.428611),4326),3785) As spere_merc;
-- the ewkt representation (wrap with ST_AsEWKT) -
SRID=3785;POINT(-13732990.8753491 6178458.96425423)
```

### See Also

Section [4.3.1](#), [ST\\_AsEWKT](#), [ST\\_Point](#), [ST\\_SRID](#), [ST\\_Transform](#), [UpdateGeometrySRID](#)

## 8.6.27 ST\_SnapToGrid

ST\_SnapToGrid — Snap all points of the input geometry to a regular grid.

### Synopsis

```
geometry ST_SnapToGrid(geometry geomA, float originX, float originY, float sizeX, float sizeY);
geometry ST_SnapToGrid(geometry geomA, float sizeX, float sizeY);
geometry ST_SnapToGrid(geometry geomA, float size);
geometry ST_SnapToGrid(geometry geomA, geometry pointOrigin, float sizeX, float sizeY, float sizeZ, float sizeM);
```

### Description

Variant 1,2,3: Snap all points of the input geometry to the grid defined by its origin and cell size. Remove consecutive points falling on the same cell, eventually returning NULL if output points are not enough to define a geometry of the given type. Collapsed geometries in a collection are stripped from it. Useful for reducing precision.

Variant 4: Introduced 1.1.0 - Snap all points of the input geometry to the grid defined by its origin (the second argument, must be a point) and cell sizes. Specify 0 as size for any dimension you don't want to snap to a grid.

#### Note

The returned geometry might lose its simplicity (see [ST\\_IsSimple](#)).

#### Note

Before release 1.1.0 this function always returned a 2d geometry. Starting at 1.1.0 the returned geometry will have same dimensionality as the input one with higher dimension values untouched. Use the version taking a second geometry argument to define all grid dimensions.

Availability: 1.0.0RC1

Availability: 1.1.0 - Z and M support

This function supports 3d and will not drop the z-index.

### Examples

```
--Snap your geometries to a precision grid of 10^-3
UPDATE mytable
 SET the_geom = ST_SnapToGrid(the_geom, 0.001);

SELECT ST_AsText(ST_SnapToGrid(
 ST_GeomFromText('LINESTRING(1.1115678 2.123, 4.111111 3.2374897, 4.11112 3.23748667) ←
 '),
 0.001)
);

LINESTRING(1.112 2.123,4.111 3.237)
--Snap a 4d geometry
SELECT ST_AsEWKT(ST_SnapToGrid(
 ST_GeomFromEWKT('LINESTRING(-1.1115678 2.123 2.3456 1.11111,
 4.111111 3.2374897 3.1234 1.1111, -1.11111112 2.123 2.3456 1.1111112)'),
```

```

ST_GeomFromEWKT('POINT(1.12 2.22 3.2 4.4444)'),
0.1, 0.1, 0.1, 0.01));
 st_asewkt

LINESTRING(-1.08 2.12 2.3 1.1144,4.12 3.22 3.1 1.1144,-1.08 2.12 2.3 1.1144)

--With a 4d geometry - the ST_SnapToGrid(geom,size) only touches x and y coords but keeps m ←
and z the same
SELECT ST_AsEWKT(ST_SnapToGrid(ST_GeomFromEWKT('LINESTRING(-1.1115678 2.123 3 2.3456,
4.111111 3.2374897 3.1234 1.1111)'),
0.01)
);
 st_asewkt

LINESTRING(-1.11 2.12 3 2.3456,4.11 3.24 3.1234 1.1111)

```

**See Also**

[ST\\_Snap](#), [ST\\_AsEWKT](#), [ST\\_AsText](#), [ST\\_GeomFromText](#), [ST\\_GeomFromEWKT](#), [ST\\_Simplify](#)

**8.6.28 ST\_Snap**

**ST\_Snap** — Snap segments and vertices of input geometry to vertices of a reference geometry.

**Synopsis**

geometry **ST\_Snap**(geometry input, geometry reference, float tolerance);

**Description**

Snaps the vertices and segments of a geometry another Geometry's vertices. A snap distance tolerance is used to control where snapping is performed. The result geometry is the input geometry with the vertices snapped. If no snapping occurs then the input geometry is returned unchanged.

Snapping one geometry to another can improve robustness for overlay operations by eliminating nearly-coincident edges (which cause problems during noding and intersection calculation).

Too much snapping can result in invalid topology being created, so the number and location of snapped vertices is decided using heuristics to determine when it is safe to snap. This can result in some potential snaps being omitted, however.

**Note**

The returned geometry might lose its simplicity (see [ST\\_IsSimple](#)) and validity (see [ST\\_IsValid](#)).

Availability: 2.0.0 requires GEOS >= 3.3.0.

**Examples**

*A multipolygon snapped to linestring to tolerance: 1.01 of distance. The new multipolygon is shown with reference linestring*

```
SELECT ST_AsText(ST_Snap(poly,line, ←
 ST_Distance(poly,line)*1.01)) AS polysnapped
FROM (SELECT
 ST_GeomFromText('MULTIPOLYGON(
 ((26 125, 26 200, 126 200, 126 125, ←
 26 125),
 (51 150, 101 150, 76 175, 51 150) ←
),
 ((151 100, 151 200, 176 175, 151 ←
 100)))') As poly,
 ST_GeomFromText('LINESTRING (5 ←
 107, 54 84, 101 100)') As line
) As foo;
```

polysnapped

```
MULTIPOLYGON(((26 125,26 200,126 200,126 ←
 125,101 100,26 125),
(51 150,101 150,76 175,51 150)),((151 ←

## 8.6.29 ST\_Transform

**ST\_Transform** — Return a new geometry with its coordinates transformed to a different spatial reference.

### Synopsis

```
geometry ST_Transform(geometry g1, integer srid);
geometry ST_Transform(geometry geom, text to_proj);
```

geometry **ST\_Transform**(geometry geom, text from\_proj, text to\_proj);  
 geometry **ST\_Transform**(geometry geom, text from\_proj, integer to\_srid);

## Description

Returns a new geometry with its coordinates transformed to a different spatial reference system. The destination spatial reference `to_srid` may be identified by a valid SRID integer parameter (i.e. it must exist in the `spatial_ref_sys` table). Alternatively, a spatial reference defined as a PROJ.4 string can be used for `to_proj` and/or `from_proj`, however these methods are not optimized. If the destination spatial reference system is expressed with a PROJ.4 string instead of an SRID, the SRID of the output geometry will be set to zero. With the exception of functions with `from_proj`, input geometries must have a defined SRID.

`ST_Transform` is often confused with `ST_SetSRID()`. `ST_Transform` actually changes the coordinates of a geometry from one spatial reference system to another, while `ST_SetSRID()` simply changes the SRID identifier of the geometry.

### Note

Requires PostGIS be compiled with Proj support. Use [PostGIS\\_Full\\_Version](#) to confirm you have proj support compiled in.

### Note

If using more than one transformation, it is useful to have a functional index on the commonly used transformations to take advantage of index usage.

### Note

Prior to 1.3.4, this function crashes if used with geometries that contain CURVES. This is fixed in 1.3.4+

Enhanced: 2.0.0 support for Polyhedral surfaces was introduced.

Enhanced: 2.3.0 support for direct PROJ.4 text was introduced.

This method implements the SQL/MM specification. SQL-MM 3: 5.1.6

This method supports Circular Strings and Curves

This function supports Polyhedral surfaces.

## Examples

Change Massachusetts state plane US feet geometry to WGS 84 long lat

```
SELECT ST_AsText(ST_Transform(ST_GeomFromText('POLYGON((743238 2967416,743238 2967450,
743265 2967450,743265.625 2967416,743238 2967416))',2249),4326)) As wgs_geom;

wgs_geom

POLYGON((-71.1776848522251 42.3902896512902,-71.1776843766326 42.3903829478009,
-71.1775844305465 42.3903826677917,-71.1775825927231 42.3902893647987,-71.177684
8522251 42.3902896512902));
(1 row)
```

```
--3D Circular String example
SELECT ST_AsEWKT(ST_Transform(ST_GeomFromEWKT('SRID=2249;CIRCULARSTRING(743238 2967416 1,743238 2967450 2,743265 2967450 3,743265.625 2967416 3,743238 2967416 4)'),4326));

 st_asewkt

SRID=4326;CIRCULARSTRING(-71.1776848522251 42.3902896512902 1,-71.1776843766326 42.3903829478009 2,
-71.1775844305465 42.3903826677917 3,
-71.1775825927231 42.3902893647987 3,-71.1776848522251 42.3902896512902 4)
```

Example of creating a partial functional index. For tables where you are not sure all the geometries will be filled in, its best to use a partial index that leaves out null geometries which will both conserve space and make your index smaller and more efficient.

```
CREATE INDEX idx_the_geom_26986_parcel
ON parcels
USING gist
(ST_Transform(the_geom, 26986))
WHERE the_geom IS NOT NULL;
```

Examples of using PROJ.4 text to transform with custom spatial references.

```
-- Find intersection of two polygons near the North pole, using a custom Gnomonic projection
-- See http://boundlessgeo.com/2012/02/flattening-the-peel/
WITH data AS (
 SELECT
 ST_GeomFromText('POLYGON((170 50,170 72,-130 72,-130 50,170 50))', 4326) AS p1,
 ST_GeomFromText('POLYGON((-170 68,-170 90,-141 90,-141 68,-170 68))', 4326) AS p2,
 '+proj=gnom +ellps=WGS84 +lat_0=70 +lon_0=-160 +no_defs'::text AS gnom
)
SELECT ST_AsText(
 ST_Transform(
 ST_Intersection(ST_Transform(p1, gnom), ST_Transform(p2, gnom)),
 gnom, 4326))
FROM data;

 st_astext

POLYGON((-170 74.053793645338,-141 73.4268621378904,-141 68,-170 68,-170 74.053793645338) ←
)
```

## Configuring transformation behaviour

Sometimes coordinate transformation involving a grid-shift can fail, for example if PROJ.4 has not been built with grid-shift files or the coordinate does not lie within the range for which the grid shift is defined. By default, PostGIS will throw an error if a grid shift file is not present, but this behaviour can be configured on a per-SRID basis either by testing different `to_proj` values of PROJ.4 text, or altering the `proj4text` value within the `spatial_ref_sys` table.

For example, the `proj4text` parameter `+datum=NAD87` is a shorthand form for the following `+nadgrids` parameter:

```
+nadgrids=@conus,@alaska,@ntv2_0.gsb,@ntv1_can.dat
```

The `@` prefix means no error is reported if the files are not present, but if the end of the list is reached with no file having been appropriate (ie. found and overlapping) then an error is issued.

If, conversely, you wanted to ensure that at least the standard files were present, but that if all files were scanned without a hit a null transformation is applied you could use:

```
+nadgrids=@conus,@alaska,@ntv2_0.gsb,@ntv1_can.dat,null
```

The null grid shift file is a valid grid shift file covering the whole world and applying no shift. So for a complete example, if you wanted to alter PostGIS so that transformations to SRID 4267 that didn't lie within the correct range did not throw an ERROR, you would use the following:

```
UPDATE spatial_ref_sys SET proj4text = '+proj=longlat +ellps=clrk66 +nadgrids=@conus, ↵
 @alaska,@ntv2_0.gsb,@ntv1_can.dat,null +no_defs' WHERE srid = 4267;
```

## 8.6.30 ST\_Translate

ST\_Translate — Translate a geometry by given offsets.

### Synopsis

```
geometry ST_Translate(geometry g1, float deltax, float deltax);
geometry ST_Translate(geometry g1, float deltax, float deltax, float deltax);
```

### Description

Returns a new geometry whose coordinates are translated delta x,delta y,delta z units. Units are based on the units defined in spatial reference (SRID) for this geometry.

#### Note

Prior to 1.3.4, this function crashes if used with geometries that contain CURVES. This is fixed in 1.3.4+

Availability: 1.2.2

This function supports 3d and will not drop the z-index.

This method supports Circular Strings and Curves

### Examples

#### Move a point 1 degree longitude

```
SELECT ST_AsText(ST_Translate(ST_GeomFromText('POINT(-71.01 42.37)',4326),1,0)) As ↵
 wgs_transgeomtxt;
```

```
wgs_transgeomtxt
```

```

POINT(-70.01 42.37)
```

#### Move a linestring 1 degree longitude and 1/2 degree latitude

```
SELECT ST_AsText(ST_Translate(ST_GeomFromText('LINESTRING(-71.01 42.37,-71.11 42.38)',4326) ↵
 ,1,0.5)) As wgs_transgeomtxt;
```

```
wgs_transgeomtxt
```

```

LINESTRING(-70.01 42.87,-70.11 42.88)
```

### Move a 3d point

```
SELECT ST_AsEWKT(ST_Translate(CAST('POINT(0 0 0)' As geometry), 5, 12,3));
st_asewkt

POINT(5 12 3)
```

### Move a curve and a point

```
SELECT ST_AsText(ST_Translate(ST_Collect('CURVEPOLYGON(CIRCULARSTRING(4 3,3.12 0.878,1 ↔
0,-1.121 5.1213,6 7, 8 9,4 3))','POINT(1 3)'),1,2));
st_astext

GEOMETRYCOLLECTION(CURVEPOLYGON(CIRCULARSTRING(5 5,4.12 2.878,2 2,-0.121 7.1213,7 9,9 11,5 ↔
5)),POINT(2 5))
```

### See Also

## 8.6.31 ST\_TransScale

`ST_TransScale` — Translate a geometry by given factors and offsets.

### Synopsis

geometry **ST\_TransScale**(geometry geomA, float deltaX, float deltaY, float XFactor, float YFactor);

### Description

Translates the geometry using the deltaX and deltaY args, then scales it using the XFactor, YFactor args, working in 2D only.

**Note**

`ST_TransScale(geomA, deltaX, deltaY, XFactor, YFactor)` is short-hand for `ST_Affine(geomA, XFactor, 0, 0, 0, YFactor, 0, 0, 0, 1, deltaX*XFactor, deltaY*YFactor, 0)`.

**Note**

Prior to 1.3.4, this function crashes if used with geometries that contain CURVES. This is fixed in 1.3.4+

Availability: 1.1.0.

This function supports 3d and will not drop the z-index.

This method supports Circular Strings and Curves

## Examples

```
SELECT ST_AsEWKT(ST_TransScale(ST_GeomFromEWKT('LINESTRING(1 2 3, 1 1 1)'), 0.5, 1, 1, 2));
 st_asewkt

LINESTRING(1.5 6 3,1.5 4 1)

--Buffer a point to get an approximation of a circle, convert to curve and then translate ↵
 1,2 and scale it 3,4
SELECT ST_AsText(ST_Transscale(ST_LineToCurve(ST_Buffer('POINT(234 567)', 3)),1,2,3,4));
 st_astext

CURVEPOLYGON(CIRCULARSTRING(714 2276,711.363961030679 2267.51471862576,705 ↵
 2264,698.636038969321 2284.48528137424,714 2276))
```

## See Also

## 8.7 Geometry Outputs

### 8.7.1 ST\_AsBinary

**ST\_AsBinary** — Return the Well-Known Binary (WKB) representation of the geometry/geography without SRID meta data.

#### Synopsis

```
bytea ST_AsBinary(geometry g1);
bytea ST_AsBinary(geometry g1, text NDR_or_XDR);
bytea ST_AsBinary(geography g1);
bytea ST_AsBinary(geography g1, text NDR_or_XDR);
```

#### Description

Returns the Well-Known Binary representation of the geometry. There are 2 variants of the function. The first variant takes no endian encoding parameter and defaults to server machine endian. The second variant takes a second argument denoting the encoding - using little-endian ('NDR') or big-endian ('XDR') encoding.

This is useful in binary cursors to pull data out of the database without converting it to a string representation.

#### Note

The WKB spec does not include the SRID. To get the WKB with SRID format use [ST\\_AsEWKB](#)

#### Note

[ST\\_AsBinary](#) is the reverse of [ST\\_GeomFromWKB](#) for geometry. Use [ST\\_GeomFromWKB](#) to convert to a postgis geometry from [ST\\_AsBinary](#) representation.

**See Also**

[ST\\_GeomFromWKB](#), [ST\\_AsEWKB](#), [ST\\_AsTWKB](#), [ST\\_AsText](#),

**8.7.2 ST\_AsEncodedPolyline**

`ST_AsEncodedPolyline` — Returns an Encoded Polyline from a `LineString` geometry.

**Synopsis**

```
text ST_AsEncodedPolyline(geometry geom, integer precision=5);
```

**Description**

Returns the geometry as an Encoded Polyline. This is a format very useful if you are using google maps

Availability: 2.2.0

**Examples****Basic**

```
SELECT ST_AsEncodedPolyline(GeomFromEWKT('SRID=4326;LINESTRING(-120.2 38.5,-120.95 40.7,-126.453 43.252)'));
--result--
|_p~iF~ps|U_ulLnnqC_mqNvxq`@
```

Use in conjunction with `geography linestring` and `geography segmentize`, and put on google maps

```
-- the SQL for Boston to San Francisco, segments every 100 KM
SELECT ST_AsEncodedPolyline(
 ST_Segmentize(
 ST_GeogFromText('LINESTRING(-71.0519 42.4935,-122.4483 37.64)'),
 100000)::geometry) As encodedFlightPath;
```

javascript will look something like this where \$ variable you replace with query result

```
<script type="text/javascript" src="http://maps.googleapis.com/maps/api/js?libraries=
 geometry"></script>
<script type="text/javascript">
 flightPath = new google.maps.Polyline({
 path: google.maps.geometry.encoding.decodePath("$encodedFlightPath"),
 map: map,
 strokeColor: '#0000CC',
 strokeOpacity: 1.0,
 strokeWeight: 4
 });
</script>
```

**See Also**

[ST\\_LineFromEncodedPolyline](#), [ST\\_Segmentize](#)

**8.7.3 ST\_AsEWKB**

`ST_AsEWKB` — Return the Well-Known Binary (WKB) representation of the geometry with SRID meta data.

## Synopsis

```
bytea ST_AsEWKB(geometry g1);
bytea ST_AsEWKB(geometry g1, text NDR_or_XDR);
```

## Description

Returns the Well-Known Binary representation of the geometry with SRID metadata. There are 2 variants of the function. The first variant takes no endian encoding parameter and defaults to little endian. The second variant takes a second argument denoting the encoding - using little-endian ('NDR') or big-endian ('XDR') encoding.

This is useful in binary cursors to pull data out of the database without converting it to a string representation.

### Note

The WKB spec does not include the SRID. To get the OGC WKB format use ST\_AsBinary

### Note

ST\_AsEWKB is the reverse of ST\_GeomFromEWKB. Use ST\_GeomFromEWKB to convert to a postgis geometry from ST\_AsEWKB representation.

Enhanced: 2.0.0 support for Polyhedral surfaces, Triangles and TIN was introduced.

This function supports 3d and will not drop the z-index.

This method supports Circular Strings and Curves

This function supports Polyhedral surfaces.

This function supports Triangles and Triangulated Irregular Network Surfaces (TIN).

## Examples

```
SELECT ST_AsEWKB(ST_GeomFromText('POLYGON((0 0,0 1,1 1,1 0,0 0))',4326));

 st_asewkb

## 8.7.4 ST\_AsEWKT

**ST\_AsEWKT** — Return the Well-Known Text (WKT) representation of the geometry with SRID meta data.

### Synopsis

```
text ST_AsEWKT(geometry g1);
text ST_AsEWKT(geography g1);
```

### Description

Returns the Well-Known Text representation of the geometry prefixed with the SRID.

#### Note

The WKT spec does not include the SRID. To get the OGC WKT format use `ST_AsText`

WKT format does not maintain precision so to prevent floating truncation, use `ST_AsBinary` or `ST_AsEWKB` format for transport.

#### Note

`ST_AsEWKT` is the reverse of `ST_GeomFromEWKT`. Use `ST_GeomFromEWKT` to convert to a postgis geometry from `ST_AsEWKT` representation.

Enhanced: 2.0.0 support for Geography, Polyhedral surfaces, Triangles and TIN was introduced.

This function supports 3d and will not drop the z-index.

This method supports Circular Strings and Curves

This function supports Polyhedral surfaces.

This function supports Triangles and Triangulated Irregular Network Surfaces (TIN).

## Examples

```
SELECT ST_AsEWKT('0103000020E61000000100000005000000000000
00
F03F000000000000F03F000000000000F03F000000000000F03
F00'::geometry);

 st_asewkt

SRID=4326;POLYGON((0 0,0 1,1 1,1 0,0 0))
(1 row)

SELECT ST_AsEWKT('010800008003000000000000000060 ↔

## 8.7.5 ST\_AsGeoJSON

`ST_AsGeoJSON` — Return the geometry as a GeoJSON element.

### Synopsis

```
text ST_AsGeoJSON(geometry geom, integer maxdecimaldigits=15, integer options=0);
text ST_AsGeoJSON(geography geog, integer maxdecimaldigits=15, integer options=0);
text ST_AsGeoJSON(integer gj_version, geometry geom, integer maxdecimaldigits=15, integer options=0);
text ST_AsGeoJSON(integer gj_version, geography geog, integer maxdecimaldigits=15, integer options=0);
```

### Description

Return the geometry as a Geometry Javascript Object Notation (GeoJSON) element. (Cf [GeoJSON specifications 1.0](#)). 2D and 3D Geometries are both supported. GeoJSON only support SFS 1.1 geometry type (no curve support for example).

The `gj_version` parameter is the major version of the GeoJSON spec. If specified, must be 1. This represents the spec version of GeoJSON.

The third argument may be used to reduce the maximum number of decimal places used in output (defaults to 15).

The last 'options' argument could be used to add Bbox or Crs in GeoJSON output:

- 0: means no option (default value)
- 1: GeoJSON Bbox
- 2: GeoJSON Short CRS (e.g EPSG:4326)
- 4: GeoJSON Long CRS (e.g urn:ogc:def:crs:EPSG::4326)

Version 1: ST\_AsGeoJSON(geom) / precision=15 version=1 options=0

Version 2: ST\_AsGeoJSON(geom, precision) / version=1 options=0

Version 3: ST\_AsGeoJSON(geom, precision, options) / version=1

Version 4: ST\_AsGeoJSON(gj\_version, geom) / precision=15 options=0

Version 5: ST\_AsGeoJSON(gj\_version, geom, precision) /options=0

Version 6: ST\_AsGeoJSON(gj\_version, geom, precision,options)

Availability: 1.3.4

Availability: 1.5.0 geography support was introduced.

Changed: 2.0.0 support default args and named args.

This function supports 3d and will not drop the z-index.

## Examples

GeoJSON format is generally more efficient than other formats for use in ajax mapping. One popular javascript client that supports this is Open Layers. Example of its use is [OpenLayers GeoJSON Example](#)

```
SELECT ST_AsGeoJSON(the_geom) from fe_edges limit 1;
 st_asgeojson

{"type":"MultiLineString","coordinates":[[[-89.734634999999997,31.492072000000000],
[-89.734955999999997,31.492237999999997]]]}

## 8.7.6 ST\_AsGML

ST\_AsGML — Return the geometry as a GML version 2 or 3 element.

### Synopsis

text **ST\_AsGML**(geometry geom, integer maxdecimaldigits=15, integer options=0);

text **ST\_AsGML**(geography geog, integer maxdecimaldigits=15, integer options=0);

text **ST\_AsGML**(integer version, geometry geom, integer maxdecimaldigits=15, integer options=0, text nprefix=null, text id=null);

text **ST\_AsGML**(integer version, geography geog, integer maxdecimaldigits=15, integer options=0, text nprefix=null, text id=null);

### Description

Return the geometry as a Geography Markup Language (GML) element. The version parameter, if specified, may be either 2 or 3. If no version parameter is specified then the default is assumed to be 2. The precision argument may be used to reduce the maximum number of decimal places (maxdecimaldigits) used in output (defaults to 15).

GML 2 refer to 2.1.2 version, GML 3 to 3.1.1 version

The 'options' argument is a bitfield. It could be used to define CRS output type in GML output, and to declare data as lat/lon:

- 0: GML Short CRS (e.g EPSG:4326), default value
- 1: GML Long CRS (e.g urn:ogc:def:crs:EPSG::4326)
- 2: For GML 3 only, remove srsDimension attribute from output.
- 4: For GML 3 only, use <LineString> rather than <Curve> tag for lines.
- 16: Declare that datas are lat/lon (e.g srid=4326). Default is to assume that data are planars. This option is useful for GML 3.1.1 output only, related to axis order. So if you set it, it will swap the coordinates so order is lat lon instead of database lon lat.
- 32: Output the box of the geometry (envelope).

The 'namespace prefix' argument may be used to specify a custom namespace prefix or no prefix (if empty). If null or omitted 'gml' prefix is used

Availability: 1.3.2

Availability: 1.5.0 geography support was introduced.

Enhanced: 2.0.0 prefix support was introduced. Option 4 for GML3 was introduced to allow using LineString instead of Curve tag for lines. GML3 Support for Polyhedral surfaces and TINS was introduced. Option 32 was introduced to output the box.

Changed: 2.0.0 use default named args

Enhanced: 2.1.0 id support was introduced, for GML 3.

#### Note

Only version 3+ of ST\_AsGML supports Polyhedral Surfaces and TINS.

This function supports 3d and will not drop the z-index.

This function supports Polyhedral surfaces.

This function supports Triangles and Triangulated Irregular Network Surfaces (TIN).

#### Examples: Version 2

```
SELECT ST_AsGML(ST_GeomFromText('POLYGON((0 0,0 1,1 1,1 0,0 0))',4326));
 st_asgml

 <gml:Polygon srsName="EPSG:4326"><gml:outerBoundaryIs><gml:LinearRing><gml:coordinates ↵
 >0,0 0,1 1,1 1,0 0,0</gml:coordinates></gml:LinearRing></gml:outerBoundaryIs></gml: ↵
 Polygon>
```

#### Examples: Version 3

```
-- Flip coordinates and output extended EPSG (16 | 1)--
SELECT ST_AsGML(3, ST_GeomFromText('POINT(5.234234233242 6.34534534534)',4326), 5, 17);
 st_asgml

 <gml:Point srsName="urn:ogc:def:crs:EPSG::4326"><gml:pos>6.34535 5.23423</gml:pos></gml: ↵
 :Point>
```

```

-- Output the envelope (32) --
SELECT ST_AsGML(3, ST_GeomFromText('LINESTRING(1 2, 3 4, 10 20)',4326), 5, 32);
 st_asgml

<gml:Envelope srsName="EPSG:4326">
 <gml:lowerCorner>1 2</gml:lowerCorner>
 <gml:upperCorner>10 20</gml:upperCorner>
</gml:Envelope>

-- Output the envelope (32) , reverse (lat lon instead of lon lat) (16), long srs (1)= 32 | ←
 16 | 1 = 49 --
SELECT ST_AsGML(3, ST_GeomFromText('LINESTRING(1 2, 3 4, 10 20)',4326), 5, 49);
 st_asgml

<gml:Envelope srsName="urn:ogc:def:crs:EPSG::4326">
 <gml:lowerCorner>2 1</gml:lowerCorner>
 <gml:upperCorner>20 10</gml:upperCorner>
</gml:Envelope>

-- Polyhedral Example --
SELECT ST_AsGML(3, ST_GeomFromEWKT('POLYHEDRALSURFACE(((0 0 0, 0 0 1, 0 1 1, 0 1 0, 0 0 0) ←
),
((0 0 0, 0 1 0, 1 1 0, 1 0 0, 0 0 0)), ((0 0 0, 1 0 0, 1 0 1, 0 0 1, 0 0 0)),
((1 1 0, 1 1 1, 1 0 1, 1 0 0, 1 1 0)),
((0 1 0, 0 1 1, 1 1 1, 1 1 0, 0 1 0)), ((0 0 1, 1 0 1, 1 1 1, 0 1 1, 0 0 1)))'));

## 8.7.7 ST\_AsHEXEWKB

**ST\_AsHEXEWKB** — Returns a Geometry in HEXEWKB format (as text) using either little-endian (NDR) or big-endian (XDR) encoding.

### Synopsis

```

text ST_AsHEXEWKB(geometry g1, text NDRorXDR);
text ST_AsHEXEWKB(geometry g1);

```

### Description

Returns a Geometry in HEXEWKB format (as text) using either little-endian (NDR) or big-endian (XDR) encoding. If no encoding is specified, then NDR is used.

#### Note

Availability: 1.2.2

This function supports 3d and will not drop the z-index.

This method supports Circular Strings and Curves

### Examples

```

SELECT ST_AsHEXEWKB(ST_GeomFromText('POLYGON((0 0,0 1,1 1,1 0,0 0))',4326));
which gives same answer as

SELECT ST_GeomFromText('POLYGON((0 0,0 1,1 1,1 0,0 0))',4326)::text;

st_ashexewkb

### 8.7.8 ST\_AsKML

ST\_AsKML — Return the geometry as a KML element. Several variants. Default version=2, default precision=15

#### Synopsis

text **ST\_AsKML**(geometry geom, integer maxdecimaldigits=15);  
text **ST\_AsKML**(geography geog, integer maxdecimaldigits=15);  
text **ST\_AsKML**(integer version, geometry geom, integer maxdecimaldigits=15, text nprefix=NULL);  
text **ST\_AsKML**(integer version, geography geog, integer maxdecimaldigits=15, text nprefix=NULL);

#### Description

Return the geometry as a Keyhole Markup Language (KML) element. There are several variants of this function. maximum number of decimal places used in output (defaults to 15), version default to 2 and default namespace is no prefix.

Version 1: ST\_AsKML(geom\_or\_geog, maxdecimaldigits) / version=2 / maxdecimaldigits=15

Version 2: ST\_AsKML(version, geom\_or\_geog, maxdecimaldigits, nprefix) maxdecimaldigits=15 / nprefix=NULL

**Note**

Requires PostGIS be compiled with Proj support. Use [PostGIS\\_Full\\_Version](#) to confirm you have proj support compiled in.

**Note**

Availability: 1.2.2 - later variants that include version param came in 1.3.2

**Note**

Enhanced: 2.0.0 - Add prefix namespace. Default is no prefix

**Note**

Changed: 2.0.0 - uses default args and supports named args

**Note**

AsKML output will not work with geometries that do not have an SRID

This function supports 3d and will not drop the z-index.

## Examples

```
SELECT ST_AsKML(ST_GeomFromText('POLYGON((0 0,0 1,1 1,1 0,0 0))',4326));

 st_askml

<Polygon><outerBoundaryIs><LinearRing><coordinates>0,0 0,1 1,1 1,0 0,0</coordinates></ ←
 LinearRing></outerBoundaryIs></Polygon>

--3d linestring
SELECT ST_AsKML('SRID=4326;LINESTRING(1 2 3, 4 5 6)');
<LineString><coordinates>1,2,3 4,5,6</coordinates></LineString>
```

## See Also

[ST\\_AsSVG](#), [ST\\_AsGML](#)

### 8.7.9 ST\_AsLatLonText

**ST\_AsLatLonText** — Return the Degrees, Minutes, Seconds representation of the given point.

#### Synopsis

```
text ST_AsLatLonText(geometry pt, text format=');
```

#### Description

Returns the Degrees, Minutes, Seconds representation of the point.

#### Note

It is assumed the point is in a lat/lon projection. The X (lon) and Y (lat) coordinates are normalized in the output to the "normal" range (-180 to +180 for lon, -90 to +90 for lat).

The text parameter is a format string containing the format for the resulting text, similar to a date format string. Valid tokens are "D" for degrees, "M" for minutes, "S" for seconds, and "C" for cardinal direction (NSEW). DMS tokens may be repeated to indicate desired width and precision ("SSS.SSSS" means "1.0023").

"M", "S", and "C" are optional. If "C" is omitted, degrees are shown with a "-" sign if south or west. If "S" is omitted, minutes will be shown as decimal with as many digits of precision as you specify. If "M" is also omitted, degrees are shown as decimal with as many digits precision as you specify.

If the format string is omitted (or zero-length) a default format will be used.

Availability: 2.0

## Examples

Default format.

```
SELECT (ST_AsLatLonText('POINT (-3.2342342 -2.32498)'));
 st_aslatlon

2\textdegree{}19'29.928"S 3\textdegree{}14'3.243"W
```

Providing a format (same as the default).

```
SELECT (ST_AsLatLonText('POINT (-3.2342342 -2.32498)', 'D\textdegree{}M'S.SSS"C'));
 st_aslatlon

2\textdegree{}19'29.928"S 3\textdegree{}14'3.243"W
```

Characters other than D, M, S, C and . are just passed through.

```
SELECT (ST_AsLatLonText('POINT (-3.2342342 -2.32498)', 'D degrees, M minutes, S seconds to the C'));
 st_aslatlon

2 degrees, 19 minutes, 30 seconds to the S 3 degrees, 14 minutes, 3 seconds to the W
```

Signed degrees instead of cardinal directions.

```
SELECT (ST_AsLatLonText('POINT (-3.2342342 -2.32498)', 'D\textdegree{}M'S.SSS"));
 st_aslatlon

-2\textdegree{}19'29.928" -3\textdegree{}14'3.243"
```

Decimal degrees.

```
SELECT (ST_AsLatLonText('POINT (-3.2342342 -2.32498)', 'D.DDDD degrees C'));
 st_aslatlon

2.3250 degrees S 3.2342 degrees W
```

Excessively large values are normalized.

```
SELECT (ST_AsLatLonText('POINT (-302.2342342 -792.32498)'));
 st_aslatlon

72\textdegree{}19'29.928"S 57\textdegree{}45'56.757"E
```

## 8.7.10 ST\_AsSVG

**ST\_AsSVG** — Returns a Geometry in SVG path data given a geometry or geography object.

### Synopsis

```
text ST_AsSVG(geometry geom, integer rel=0, integer maxdecimaldigits=15);
text ST_AsSVG(geography geog, integer rel=0, integer maxdecimaldigits=15);
```

### Description

Return the geometry as Scalar Vector Graphics (SVG) path data. Use 1 as second argument to have the path data implemented in terms of relative moves, the default (or 0) uses absolute moves. Third argument may be used to reduce the maximum number of decimal digits used in output (defaults to 15). Point geometries will be rendered as cx/cy when 'rel' arg is 0, x/y when 'rel' is 1. Multipoint geometries are delimited by commas (","), GeometryCollection geometries are delimited by semicolons (";").

#### Note

Availability: 1.2.2. Availability: 1.4.0 Changed in PostGIS 1.4.0 to include L command in absolute path to conform to <http://www.w3.org/TR/SVG/paths.html#PathDataBNF>

Changed: 2.0.0 to use default args and support named args

Examples

```
SELECT ST_AsSVG(ST_GeomFromText('POLYGON((0 0,0 1,1 1,1 0,0 0))',4326));
```

|                         |
|-------------------------|
| st_assvg                |
| -----                   |
| M 0 0 L 0 -1 1 -1 1 0 Z |

### 8.7.11 ST\_AsText

ST\_AsText — Return the Well-Known Text (WKT) representation of the geometry/geography without SRID metadata.

Synopsis

```
text ST_AsText(geometry g1);
text ST_AsText(geography g1);
```

Description

Returns the Well-Known Text representation of the geometry/geography.

---

 **Note**  
The WKT spec does not include the SRID. To get the SRID as part of the data, use the non-standard PostGIS [ST\\_AsEWKT](#)

---

 WKT format does not maintain precision so to prevent floating truncation, use ST\_AsBinary or ST\_AsEWKB format for transport.

---

 **Note**  
ST\_AsText is the reverse of [ST\\_GeomFromText](#). Use [ST\\_GeomFromText](#) to convert to a postgis geometry from ST\_AsText representation.

---

Availability: 1.5 - support for geography was introduced.

-  This method implements the [OpenGIS Simple Features Implementation Specification for SQL 1.1](#). s2.1.1.1
-  This method implements the SQL/MM specification. SQL-MM 3: 5.1.25
-  This method supports Circular Strings and Curves

Examples

```
SELECT ST_AsText('01030000000100000005000000000000000000000000
00
F03F000000000000F03F000000000000F03F000000000000F03
F00');
```

```

st_astext

POLYGON((0 0,0 1,1 1,1 0,0 0))
(1 row)

```

### See Also

## 8.7.12 ST\_AsTWKB

**ST\_AsTWKB** — Returns the geometry as TWKB, aka "Tiny Well-Known Binary"

### Synopsis

bytea **ST\_AsTWKB**(geometry g1, integer decimaldigits\_xy=0, integer decimaldigits\_z=0, integer decimaldigits\_m=0, boolean include\_sizes=false, boolean include\_bounding\_boxes=false);

bytea **ST\_AsTWKB**(geometry[] geometries, bigint[] unique\_ids, integer decimaldigits\_xy=0, integer decimaldigits\_z=0, integer decimaldigits\_m=0, boolean include\_sizes=false, boolean include\_bounding\_boxes=false);

### Description

Returns the geometry in TWKB (Tiny Well-Known Binary) format. TWKB is a **compressed binary format** with a focus on minimizing the size of the output.

The decimal digits parameters control how much precision is stored in the output. By default, values are rounded to the nearest unit before encoding. If you want to transfer more precision, increase the number. For example, a value of 1 implies that the first digit to the right of the decimal point will be preserved.

The sizes and bounding boxes parameters control whether optional information about the encoded length of the object and the bounds of the object are included in the output. By default they are not. Do not turn them on unless your client software has a use for them, as they just use up space (and saving space is the point of TWKB).

The array-input form of the function is used to convert a collection of geometries and unique identifiers into a TWKB collection that preserves the identifiers. This is useful for clients that expect to unpack a collection and then access further information about the objects inside. You can create the arrays using the [array\\_agg](#) function. The other parameters operate the same as for the simple form of the function.

#### Note

The format specification is available online at <https://github.com/TWKB/Specification>, and code for building a JavaScript client can be found at <https://github.com/TWKB/twkb.js>.

Availability: 2.2.0

### Examples

```

SELECT ST_AsTWKB('LINESTRING(1 1,5 5)::geometry');
 st_astwkb

```

```

\x02000202020808

```

To create an aggregate TWKB object including identifiers aggregate the desired geometries and objects first, using "array\_agg()", then call the appropriate TWKB function.

```
SELECT ST_AsTWKB(array_agg(geom), array_agg(gid)) FROM mytable;
 st_astwkb

\x040402020400000202
```

**See Also**

**8.7.13 ST\_AsX3D**

ST\_AsX3D — Returns a Geometry in X3D xml node element format: ISO-IEC-19776-1.2-X3DEncodings-XML

**Synopsis**

text **ST\_AsX3D**(geometry g1, integer maxdecimaldigits=15, integer options=0);

**Description**

Returns a geometry as an X3D xml formatted node element <http://www.web3d.org/standards/number/19776-1>. If maxdecimaldigits (precision) is not specified then defaults to 15.

**Note**

There are various options for translating PostGIS geometries to X3D since X3D geometry types don't map directly to PostGIS geometry types and some newer X3D types that might be better mappings we have avoided since most rendering tools don't currently support them. These are the mappings we have settled on. Feel free to post a bug ticket if you have thoughts on the idea or ways we can allow people to denote their preferred mappings. Below is how we currently map PostGIS 2D/3D types to X3D types

The 'options' argument is a bitfield. For PostGIS 2.2+, this is used to denote whether to represent coordinates with X3D GeoCoordinates Geospatial node and also whether to flip the x/y axis. By default, ST\_AsX3D outputs in database form (long,lat or X,Y), but X3D default of lat/lon, y/x may be preferred.

- 0: X/Y in database order (e.g. long/lat = X,Y is standard database order), default value, and non-spatial coordinates (just regular old Coordinate tag).
- 1: Flip X and Y. If used in conjunction with the GeoCoordinate option switch, then output will be default "latitude\_first" and coordinates will be flipped as well.
- 2: Output coordinates in GeoSpatial GeoCoordinates. This option will throw an error if geometries are not in WGS 84 long lat (srid: 4326). This is currently the only GeoCoordinate type supported. Refer to X3D specs specifying a spatial reference system.. Default output will be GeoCoordinate geoSystem="GD" "WE" "longitude\_first". If you prefer the X3D default of GeoCoordinate geoSystem="GD" "WE" "latitude\_first" use (2 + 1) = 3

| PostGIS Type    | 2D X3D Type                              | 3D X3D Type    |
|-----------------|------------------------------------------|----------------|
| LINestring      | not yet implemented - will be PolyLine2D | LineSet        |
| MULTILINEstring | not yet implemented - will be PolyLine2D | IndexedLineSet |
| MULTIPOINT      | Polypoint2D                              | PointSet       |

| PostGIS Type                       | 2D X3D Type                             | 3D X3D Type                                                       |
|------------------------------------|-----------------------------------------|-------------------------------------------------------------------|
| POINT                              | outputs the space delimited coordinates | outputs the space delimited coordinates                           |
| (MULTI) POLYGON, POLYHEDRALSURFACE | Invalid X3D markup                      | IndexedFaceSet (inner rings currently output as another facetset) |
| TIN                                | TriangleSet2D (Not Yet Implemented)     | IndexedTriangleSet                                                |

**Note**

2D geometry support not yet complete. Inner rings currently just drawn as separate polygons. We are working on these.

Lots of advancements happening in 3D space particularly with [X3D Integration with HTML5](#)

There is also a nice open source X3D viewer you can use to view rendered geometries. Free Wrl <http://freewrl.sourceforge.net/> binaries available for Mac, Linux, and Windows. Use the FreeWRL\_Launcher packaged to view the geometries.

Also check out [PostGIS minimalist X3D viewer](#) that utilizes this function and [x3dDom html/js open source toolkit](#).

Availability: 2.0.0: ISO-IEC-19776-1.2-X3DEncodings-XML

Enhanced: 2.2.0: Support for GeoCoordinates and axis (x/y, long/lat) flipping. Look at options for details.

This function supports 3d and will not drop the z-index.

This function supports Polyhedral surfaces.

This function supports Triangles and Triangulated Irregular Network Surfaces (TIN).

**Example: Create a fully functional X3D document - This will generate a cube that is viewable in FreeWrl and other X3D viewers.**

```
SELECT '<?xml version="1.0" encoding="UTF-8"?>

 16 10 12 0 10 8 8 10 0 12 10 -8 8 10 -8 0 10 -8 -4 10 0 -8 10 8 -4 10 ' />
</IndexedLineSet>

```

### 8.7.14 ST\_GeoHash

ST\_GeoHash — Return a GeoHash representation of the geometry.

#### Synopsis

text **ST\_GeoHash**(geometry geom, integer maxchars=full\_precision\_of\_point);

#### Description

Return a GeoHash representation (<http://en.wikipedia.org/wiki/Geohash>) of the geometry. A GeoHash encodes a point into a text form that is sortable and searchable based on prefixing. A shorter GeoHash is a less precise representation of a point. It can also be thought of as a box, that contains the actual point.

If no `maxchars` is specified ST\_GeoHash returns a GeoHash based on full precision of the input geometry type. Points return a GeoHash with 20 characters of precision (about enough to hold the full double precision of the input). Other types return a GeoHash with a variable amount of precision, based on the size of the feature. Larger features are represented with less precision, smaller features with more precision. The idea is that the box implied by the GeoHash will always contain the input feature.

If `maxchars` is specified ST\_GeoHash returns a GeoHash with at most that many characters so a possibly lower precision representation of the input geometry. For non-points, the starting point of the calculation is the center of the bounding box of the geometry.

Availability: 1.4.0

#### Note

ST\_GeoHash will not work with geometries that are not in geographic (lon/lat) coordinates.

This method supports Circular Strings and Curves

#### Examples

```

SELECT ST_GeoHash(ST_SetSRID(ST_MakePoint(-126,48),4326));

 st_geohash

c0w3hf1s70w3hf1s70w3

SELECT ST_GeoHash(ST_SetSRID(ST_MakePoint(-126,48),4326),5);

```

```
st_geohash
```

```

c0w3h
```

## 8.8 Operators

### 8.8.1 &&

**&&** — Returns `TRUE` if A's 2D bounding box intersects B's 2D bounding box.

#### Synopsis

```
boolean &&(geometry A , geometry B);
boolean &&(geography A , geography B);
```

#### Description

The **&&** operator returns `TRUE` if the 2D bounding box of geometry A intersects the 2D bounding box of geometry B.

#### Note

This operand will make use of any indexes that may be available on the geometries.

Enhanced: 2.0.0 support for Polyhedral surfaces was introduced.

Availability: 1.5.0 support for geography was introduced.

This method supports Circular Strings and Curves

This function supports Polyhedral surfaces.

#### Examples

```
SELECT tbl1.column1, tbl2.column1, tbl1.column2 && tbl2.column2 AS overlaps
FROM (VALUES
 (1, 'LINESTRING(0 0, 3 3)::geometry),
 (2, 'LINESTRING(0 1, 0 5)::geometry)) AS tbl1,
(VALUES
 (3, 'LINESTRING(1 2, 4 6)::geometry)) AS tbl2;
```

```
column1 | column1 | overlaps
-----+-----
 1 | 3 | t
 2 | 3 | f
(2 rows)
```

**See Also**

**8.8.2 &&(geometry,box2df)**

`&&(geometry,box2df)` — Returns `TRUE` if a geometry's (cached) 2D bounding box intersects a 2D float precision bounding box (`BOX2DF`).

**Synopsis**

boolean `&&( geometry A , box2df B );`

**Description**

The `&&` operator returns `TRUE` if the cached 2D bounding box of geometry `A` intersects the 2D bounding box `B`, using float precision. This means that if `B` is a (double precision) `box2d`, it will be internally converted to a float precision 2D bounding box (`BOX2DF`)

**Note**

This operand is intended to be used internally by BRIN indexes, more than by users.

Availability: 2.3.0 support for Block Range INdexes (BRIN) was introduced. Requires PostgreSQL 9.5+.

This method supports Circular Strings and Curves

This function supports Polyhedral surfaces.

**Examples**

```
SELECT ST_MakePoint(1,1) && ST_MakeBox2D(ST_MakePoint(0,0), ST_MakePoint(2,2)) AS overlaps;
```

```
overlaps

t
(1 row)
```

**8.8.3 &&(box2df,geometry)**

`&&(box2df,geometry)` — Returns `TRUE` if a 2D float precision bounding box (`BOX2DF`) intersects a geometry's (cached) 2D bounding box.

## Synopsis

boolean **&&**( box2df A , geometry B );

## Description

The **&&** operator returns `TRUE` if the 2D bounding box A intersects the cached 2D bounding box of geometry B, using float precision. This means that if A is a (double precision) box2d, it will be internally converted to a float precision 2D bounding box (BOX2DF)

### Note

This operand is intended to be used internally by BRIN indexes, more than by users.

Availability: 2.3.0 support for Block Range INdexes (BRIN) was introduced. Requires PostgreSQL 9.5+.

This method supports Circular Strings and Curves

This function supports Polyhedral surfaces.

## Examples

```
SELECT ST_MakeBox2D(ST_MakePoint(0,0), ST_MakePoint(2,2)) && ST_MakePoint(1,1) AS overlaps;

overlaps

t
(1 row)
```

### 8.8.4 &&(box2df,box2df)

**&&(box2df,box2df)** — Returns `TRUE` if two 2D float precision bounding boxes (BOX2DF) intersect each other.

## Synopsis

boolean **&&**( box2df A , box2df B );

## Description

The **&&** operator returns `TRUE` if two 2D bounding boxes A and B intersect each other, using float precision. This means that if A (or B) is a (double precision) box2d, it will be internally converted to a float precision 2D bounding box (BOX2DF)

**Note**

This operator is intended to be used internally by BRIN indexes, more than by users.

Availability: 2.3.0 support for Block Range INdexes (BRIN) was introduced. Requires PostgreSQL 9.5+.

This method supports Circular Strings and Curves

This function supports Polyhedral surfaces.

**Examples**

```
SELECT ST_MakeBox2D(ST_MakePoint(0,0), ST_MakePoint(2,2)) && ST_MakeBox2D(ST_MakePoint(1,1) ←
, ST_MakePoint(3,3)) AS overlaps;
```

```
overlaps

t
(1 row)
```

**8.8.5 &&&**

**&&&** — Returns TRUE if A's n-D bounding box intersects B's n-D bounding box.

**Synopsis**

boolean **&&&**( geometry A , geometry B );

**Description**

The **&&&** operator returns TRUE if the n-D bounding box of geometry A intersects the n-D bounding box of geometry B.

**Note**

This operand will make use of any indexes that may be available on the geometries.

Availability: 2.0.0

This method supports Circular Strings and Curves

This function supports Polyhedral surfaces.

This function supports Triangles and Triangulated Irregular Network Surfaces (TIN).

This function supports 3d and will not drop the z-index.

**Examples: 3D LineStrings**

```
SELECT tbl1.column1, tbl2.column1, tbl1.column2 &&& tbl2.column2 AS overlaps_3d,
 tbl1.column2 && tbl2.column2 AS overlaps_2d
FROM (VALUES
 (1, 'LINESTRING Z(0 0 1, 3 3 2)::geometry),
 (2, 'LINESTRING Z(1 2 0, 0 5 -1)::geometry)) AS tbl1,
(VALUES
 (3, 'LINESTRING Z(1 2 1, 4 6 1)::geometry)) AS tbl2;

column1 | column1 | overlaps_3d | overlaps_2d
-----+-----+-----+-----
 1 | 3 | t | t
 2 | 3 | f | t
```

**Examples: 3M LineStrings**

```
SELECT tbl1.column1, tbl2.column1, tbl1.column2 &&& tbl2.column2 AS overlaps_3zm,
 tbl1.column2 && tbl2.column2 AS overlaps_2d
FROM (VALUES
 (1, 'LINESTRING M(0 0 1, 3 3 2)::geometry),
 (2, 'LINESTRING M(1 2 0, 0 5 -1)::geometry)) AS tbl1,
(VALUES
 (3, 'LINESTRING M(1 2 1, 4 6 1)::geometry)) AS tbl2;

column1 | column1 | overlaps_3zm | overlaps_2d
-----+-----+-----+-----
 1 | 3 | t | t
 2 | 3 | f | t
```

**See Also****&&****8.8.6 &&&(geometry,gidx)**

**&&&(geometry,gidx)** — Returns TRUE if a geometry's (cached) n-D bounding box intersects a n-D float precision bounding box (GIDX).

**Synopsis**

```
boolean &&&(geometry A , gidx B);
```

**Description**

The **&&&** operator returns TRUE if the cached n-D bounding box of geometry A intersects the n-D bounding box B, using float precision. This means that if B is a (double precision) box3d, it will be internally converted to a float precision 3D bounding box (GIDX)

**Note**

This operator is intended to be used internally by BRIN indexes, more than by users.

Availability: 2.3.0 support for Block Range INdexes (BRIN) was introduced. Requires PostgreSQL 9.5+.

This method supports Circular Strings and Curves

This function supports Polyhedral surfaces.

This function supports Triangles and Triangulated Irregular Network Surfaces (TIN).

This function supports 3d and will not drop the z-index.

## Examples

```
SELECT ST_MakePoint(1,1,1) &&& ST_3DMakeBox(ST_MakePoint(0,0,0), ST_MakePoint(2,2,2)) AS ↔
 overlaps;

overlaps

### 8.8.9 &<

**&<** — Returns TRUE if A's bounding box overlaps or is to the left of B's.

## Synopsis

boolean **&<**( geometry A , geometry B );

## Description

The **&<** operator returns TRUE if the bounding box of geometry A overlaps or is to the left of the bounding box of geometry B, or more accurately, overlaps or is NOT to the right of the bounding box of geometry B.

### Note

This operand will make use of any indexes that may be available on the geometries.

## Examples

```
SELECT tbl1.column1, tbl2.column1, tbl1.column2 &< tbl2.column2 AS overleft
FROM
 (VALUES
 (1, 'LINESTRING(1 2, 4 6)::geometry) AS tbl1,
 (VALUES
 (2, 'LINESTRING(0 0, 3 3)::geometry),
 (3, 'LINESTRING(0 1, 0 5)::geometry),
 (4, 'LINESTRING(6 0, 6 1)::geometry) AS tbl2;
```

```

### 8.8.10 &<|

`&<|` — Returns TRUE if A's bounding box overlaps or is below B's.

#### Synopsis

boolean `&<|( geometry A , geometry B );`

#### Description

The `&<|` operator returns TRUE if the bounding box of geometry A overlaps or is below of the bounding box of geometry B, or more accurately, overlaps or is NOT above the bounding box of geometry B.

This method supports Circular Strings and Curves

This function supports Polyhedral surfaces.

#### Note

This operand will make use of any indexes that may be available on the geometries.

#### Examples

```
SELECT tbl1.column1, tbl2.column1, tbl1.column2 &<| tbl2.column2 AS overbelow
FROM
 (VALUES
 (1, 'LINESTRING(6 0, 6 4)::geometry) AS tbl1,
 (VALUES
 (2, 'LINESTRING(0 0, 3 3)::geometry),
 (3, 'LINESTRING(0 1, 0 5)::geometry),
 (4, 'LINESTRING(1 2, 4 6)::geometry) AS tbl2;

1	2	t
1	3	f
1	4	f

(3 rows)

**See Also**

&lt;&lt;, &gt;&gt;, |&gt;&gt;

**8.8.14 =**

= — Returns TRUE if A's bounding box is the same as B's. Uses double precision bounding box.

**Synopsis**

```
boolean =(geometry A , geometry B);
boolean =(geography A , geography B);
```

**Description**

The = operator returns TRUE if the bounding box of geometry/geography A is the same as the bounding box of geometry/geography B. PostgreSQL uses the =, <, and > operators defined for geometries to perform internal orderings and comparison of geometries (ie. in a GROUP BY or ORDER BY clause).

**Warning**

This is cause for a lot of confusion. When you compare geometryA = geometryB it will return true even when the geometries are clearly different IF their bounding boxes are the same. To check for true equality use [ST\\_OrderingEquals](#) or [ST\\_Equals](#)

**Caution**

This operand will NOT make use of any indexes that may be available on the geometries.

This method supports Circular Strings and Curves

This function supports Polyhedral surfaces.

Changed: 2.0.0 , the bounding box of geometries was changed to use double precision instead of float4 precision of prior. The side effect of this is that in particular points in prior versions that were a little different may have returned true in prior versions and false in 2.0+ since their float4 boxes would be the same but there float8 (double precision), would be different.

**Examples**

```
SELECT 'LINESTRING(0 0, 0 1, 1 0)::geometry = 'LINESTRING(1 1, 0 0)::geometry;
?column?

t
(1 row)

SELECT ST_AsText(column1)
FROM (VALUES
 ('LINESTRING(0 0, 1 1)::geometry),
 ('LINESTRING(1 1, 0 0)::geometry)) AS foo;
 st_astext

```

```

LINESTRING(0 0,1 1)
LINESTRING(1 1,0 0)
(2 rows)

-- Note: the GROUP BY uses the "=" to compare for geometry equivalency.
SELECT ST_AsText(column1)
FROM (VALUES
 ('LINESTRING(0 0, 1 1)::geometry),
 ('LINESTRING(1 1, 0 0)::geometry)) AS foo
GROUP BY column1;
 st_astext

LINESTRING(0 0,1 1)
(1 row)

-- In versions prior to 2.0, this used to return true --
SELECT ST_GeomFromText('POINT(1707296.37 4820536.77)') =
 ST_GeomFromText('POINT(1707296.27 4820536.87)') As pt_intersect;

--pt_intersect --
f

```

### 8.8.17 @(geometry,box2df)

@(geometry,box2df) — Returns TRUE if a geometry's 2D bounding box is contained into a 2D float precision bounding box (BOX2DF).

#### Synopsis

```
boolean @(geometry A , box2df B);
```

#### Description

The @ operator returns TRUE if the A geometry's 2D bounding box is contained the 2D bounding box B, using float precision. This means that if B is a (double precision) box2d, it will be internally converted to a float precision 2D bounding box (BOX2DF)

#### Note

This operand is intended to be used internally by BRIN indexes, more than by users.

Availability: 2.3.0 support for Block Range INdexes (BRIN) was introduced. Requires PostgreSQL 9.5+.

This method supports Circular Strings and Curves

This function supports Polyhedral surfaces.

#### Examples

```
SELECT ST_Buffer(ST_GeomFromText('POINT(2 2)'), 1) @ ST_MakeBox2D(ST_MakePoint(0,0), ↔
 ST_MakePoint(5,5)) AS is_contained;
```

```

### 8.8.18 @(box2df,geometry)

@(box2df,geometry) — Returns TRUE if a 2D float precision bounding box (BOX2DF) is contained into a geometry's 2D bounding box.

#### Synopsis

```
boolean @(box2df A , geometry B);
```

## Description

The @ operator returns TRUE if the 2D bounding box A is contained into the B geometry's 2D bounding box, using float precision. This means that if B is a (double precision) box2d, it will be internally converted to a float precision 2D bounding box (BOX2DF)

### Note

This operand is intended to be used internally by BRIN indexes, more than by users.

Availability: 2.3.0 support for Block Range INdexes (BRIN) was introduced. Requires PostgreSQL 9.5+.

This method supports Circular Strings and Curves

This function supports Polyhedral surfaces.

## Examples

```
SELECT ST_MakeBox2D(ST_MakePoint(2,2), ST_MakePoint(3,3)) @ ST_Buffer(ST_GeomFromText(' ↵
POINT(1 1)'), 10) AS is_contained;
```

```
is_contained

t
(1 row)
```

### 8.8.19 @(box2df,box2df)

@(box2df,box2df) — Returns TRUE if a 2D float precision bounding box (BOX2DF) is contained into another 2D float precision bounding box.

## Synopsis

```
boolean @(box2df A , box2df B);
```

## Description

The @ operator returns TRUE if the 2D bounding box A is contained into the 2D bounding box B, using float precision. This means that if A (or B) is a (double precision) box2d, it will be internally converted to a float precision 2D bounding box (BOX2DF)

### Note

This operand is intended to be used internally by BRIN indexes, more than by users.

Availability: 2.3.0 support for Block Range INdices (BRIN) was introduced. Requires PostgreSQL 9.5+.

This method supports Circular Strings and Curves

This function supports Polyhedral surfaces.

### Examples

```
SELECT ST_MakeBox2D(ST_MakePoint(2,2), ST_MakePoint(3,3)) @ ST_MakeBox2D(ST_MakePoint(0,0), ←
 ST_MakePoint(5,5)) AS is_contained;
```

```
is_contained

t
(1 row)
```

### 8.8.20 |&>

|&> — Returns TRUE if A's bounding box overlaps or is above B's.

#### Synopsis

boolean |&>( geometry A , geometry B );

#### Description

The |&> operator returns TRUE if the bounding box of geometry A overlaps or is above the bounding box of geometry B, or more accurately, overlaps or is NOT below the bounding box of geometry B.

#### Note

This operand will make use of any indexes that may be available on the geometries.

### Examples

```
SELECT tbl1.column1, tbl2.column1, tbl1.column2 |&> tbl2.column2 AS overabove
FROM
 (VALUES
 (1, 'LINESTRING(6 0, 6 4)::geometry) AS tbl1,
 (VALUES
 (2, 'LINESTRING(0 0, 3 3)::geometry),
 (3, 'LINESTRING(0 1, 0 5)::geometry),
 (4, 'LINESTRING(1 2, 4 6)::geometry) AS tbl2;
```

```
column1 | column1 | overabove
```

```

### 8.8.21 |>>

|>> — Returns TRUE if A's bounding box is strictly above B's.

### Synopsis

```
boolean |>>(geometry A , geometry B);
```

### Description

The |>> operator returns TRUE if the bounding box of geometry A is strictly to the right of the bounding box of geometry B.

#### Note

This operand will make use of any indexes that may be available on the geometries.

### Examples

```

SELECT tbl1.column1, tbl2.column1, tbl1.column2 |>> tbl2.column2 AS above
FROM
 (VALUES
 (1, 'LINESTRING (1 4, 1 7)::geometry) AS tbl1,
 (VALUES
 (2, 'LINESTRING (0 0, 4 2)::geometry),
 (3, 'LINESTRING (6 1, 6 5)::geometry),
 (4, 'LINESTRING (2 3, 5 6)::geometry) AS tbl2;

```

```

### 8.8.22 ~

~ — Returns TRUE if A's bounding box contains B's.

**Synopsis**

```
boolean ~(geometry A , geometry B);
```

**Description**

The ~ operator returns TRUE if the bounding box of geometry A completely contains the bounding box of geometry B.

**Note**

This operand will make use of any indexes that may be available on the geometries.

**Examples**

```
SELECT tbl1.column1, tbl2.column1, tbl1.column2 ~ tbl2.column2 AS contains
FROM
 (VALUES
 (1, 'LINESTRING (0 0, 3 3)::geometry) AS tbl1,
 (VALUES
 (2, 'LINESTRING (0 0, 4 4)::geometry),
 (3, 'LINESTRING (1 1, 2 2)::geometry),
 (4, 'LINESTRING (0 0, 3 3)::geometry) AS tbl2;
```

column1	column1	contains

**8.8.23 ~(geometry,box2df)**

~(geometry,box2df) — Returns TRUE if a geometry's 2D bonding box contains a 2D float precision bounding box (GIDX).

**Synopsis**

```
boolean ~(geometry A , box2df B);
```

**Description**

The ~ operator returns TRUE if the 2D bounding box of a geometry A contains the 2D bounding box B, using float precision. This means that if B is a (double precision) box2d, it will be internally converted to a float precision 2D bounding box (BOX2DF)

**Note**

This operand is intended to be used internally by BRIN indexes, more than by users.

Availability: 2.3.0 support for Block Range INdexes (BRIN) was introduced. Requires PostgreSQL 9.5+.

This method supports Circular Strings and Curves

This function supports Polyhedral surfaces.

### Examples

```
SELECT ST_Buffer(ST_GeomFromText('POINT(1 1)'), 10) ~ ST_MakeBox2D(ST_MakePoint(0,0), ↔
 ST_MakePoint(2,2)) AS contains;
```

### 8.8.24 ~(box2df,geometry)

`~(box2df,geometry)` — Returns `TRUE` if a 2D float precision bounding box (BOX2DF) contains a geometry's 2D bonding box.

### Synopsis

```
boolean ~(box2df A , geometry B);
```

### Description

The `~` operator returns `TRUE` if the 2D bounding box `A` contains the `B` geometry's bounding box, using float precision. This means that if `A` is a (double precision) `box2d`, it will be internally converted to a float precision 2D bounding box (BOX2DF)

#### Note

This operand is intended to be used internally by BRIN indexes, more than by users.

Availability: 2.3.0 support for Block Range INdexes (BRIN) was introduced. Requires PostgreSQL 9.5+.

This method supports Circular Strings and Curves

This function supports Polyhedral surfaces.

## Examples

```
SELECT ST_MakeBox2D(ST_MakePoint(0,0), ST_MakePoint(5,5)) ~ ST_Buffer(ST_GeomFromText(' ↵
POINT(2 2)'), 1) AS contains;
```

```

### 8.8.25 ~(box2df,box2df)

~(box2df,box2df) — Returns TRUE if a 2D float precision bounding box (BOX2DF) contains another 2D float precision bounding box (BOX2DF).

## Synopsis

```
boolean ~(box2df A , box2df B);
```

## Description

The ~ operator returns TRUE if the 2D bounding box A contains the 2D bounding box B, using float precision. This means that if A is a (double precision) box2d, it will be internally converted to a float precision 2D bounding box (BOX2DF)

### Note

This operand is intended to be used internally by BRIN indexes, more than by users.

Availability: 2.3.0 support for Block Range INdexes (BRIN) was introduced. Requires PostgreSQL 9.5+.

This method supports Circular Strings and Curves

This function supports Polyhedral surfaces.

## Examples

```
SELECT ST_MakeBox2D(ST_MakePoint(0,0), ST_MakePoint(5,5)) ~ ST_MakeBox2D(ST_MakePoint(2,2), ↵
ST_MakePoint(3,3)) AS contains;
```

```
contains

**8.8.26 ~=**

`~=` — Returns TRUE if A's bounding box is the same as B's.

**Synopsis**

```
boolean ~= (geometry A , geometry B);
```

**Description**

The `~=` operator returns TRUE if the bounding box of geometry/geography A is the same as the bounding box of geometry/geography B.

**Note**

This operand will make use of any indexes that may be available on the geometries.

Availability: 1.5.0 changed behavior

This function supports Polyhedral surfaces.

**Warning**

This operator has changed behavior in PostGIS 1.5 from testing for actual geometric equality to only checking for bounding box equality. To complicate things it also depends on if you have done a hard or soft upgrade which behavior your database has. To find out which behavior your database has you can run the query below. To check for true equality use [ST\\_OrderingEquals](#) or [ST\\_Equals](#) and to check for bounding box equality `=`; operator is a safer option.

**Examples**

```
select 'LINESTRING(0 0, 1 1)::geometry ~= 'LINESTRING(0 1, 1 0)::geometry as equality;
equality |
-----+
t |
```

The above can be used to test if you have the new or old behavior of `~=` operator.

**See Also**

[ST\\_Equals](#), [ST\\_OrderingEquals](#), [=](#)

**8.8.27 <->**

`<->` — Returns the 2D distance between A and B.

## Synopsis

```
double precision <->(geometry A , geometry B);
double precision <->(geography A , geography B);
```

## Description

The <-> operator returns the 2D distance between two geometries. Used in the "ORDER BY" clause provides index-assisted nearest-neighbor result sets. For PostgreSQL below 9.5 only gives centroid distance of bounding boxes and for PostgreSQL 9.5+, does true KNN distance search giving true distance between geometries, and distance sphere for geographies.

### Note

This operand will make use of 2D GiST indexes that may be available on the geometries. It is different from other operators that use spatial indexes in that the spatial index is only used when the operator is in the ORDER BY clause.

### Note

Index only kicks in if one of the geometries is a constant (not in a subquery/cte). e.g. 'SRID=3005;POINT(1011102 450541)::geometry' instead of a.geom

Refer to [OpenGeo workshop: Nearest-Neighbour Searching](#) for real live example.

Enhanced: 2.2.0 -- True KNN ("K nearest neighbor") behavior for geometry and geography for PostgreSQL 9.5+. Note for geography KNN is based on sphere rather than spheroid. For PostgreSQL 9.4 and below, geography support is new but only supports centroid box.

Changed: 2.2.0 -- For PostgreSQL 9.5 users, old Hybrid syntax may be slower, so you'll want to get rid of that hack if you are running your code only on PostGIS 2.2+ 9.5+. See examples below.

Availability: 2.0.0 -- Weak KNN provides nearest neighbors based on geometry centroid distances instead of true distances. Exact results for points, inexact for all other types. Available for PostgreSQL 9.1+

## Examples

```
SELECT ST_Distance(geom, 'SRID=3005;POINT(1011102 450541)::geometry') as d,edabbr, vaabbr
FROM va2005
ORDER BY d limit 10;
```

d	edabbr	vaabbr
0	ALQ	128
5541.57712511724	ALQ	129A
5579.67450712005	ALQ	001
6083.4207708641	ALQ	131
7691.2205404848	ALQ	003
7900.75451037313	ALQ	122
8694.20710669982	ALQ	129B
9564.24289057111	ALQ	130
12089.665931705	ALQ	127
18472.5531479404	ALQ	002

(10 rows)

Then the KNN raw answer:

```
SELECT st_distance(geom, 'SRID=3005;POINT(1011102 450541)::geometry) as d,edabbr, vaabbr
FROM va2005
ORDER BY geom <-> 'SRID=3005;POINT(1011102 450541)::geometry limit 10;
```

d	edabbr	vaabbr
0	ALQ	128
5541.57712511724	ALQ	129A
5579.67450712005	ALQ	001
6083.4207708641	ALQ	131
7691.2205404848	ALQ	003
7900.75451037313	ALQ	122
8694.20710669982	ALQ	129B
9564.24289057111	ALQ	130
12089.665931705	ALQ	127
18472.5531479404	ALQ	002

(10 rows)

If you run "EXPLAIN ANALYZE" on the two queries you would see a performance improvement for the second.

For users running with PostgreSQL < 9.5, use a hybrid query to find the true nearest neighbors. First a CTE query using the index-assisted KNN, then an exact query to get correct ordering:

```
WITH index_query AS (
 SELECT ST_Distance(geom, 'SRID=3005;POINT(1011102 450541)::geometry) as d,edabbr, vaabbr
 FROM va2005
 ORDER BY geom <-> 'SRID=3005;POINT(1011102 450541)::geometry LIMIT 100)
SELECT *
FROM index_query
ORDER BY d limit 10;
```

d	edabbr	vaabbr
0	ALQ	128
5541.57712511724	ALQ	129A
5579.67450712005	ALQ	001
6083.4207708641	ALQ	131
7691.2205404848	ALQ	003
7900.75451037313	ALQ	122
8694.20710669982	ALQ	129B
9564.24289057111	ALQ	130
12089.665931705	ALQ	127
18472.5531479404	ALQ	002

(10 rows)

## See Also

## 8.8.28 |=

**|=** — Returns the distance between A and B trajectories at their closest point of approach.

### Synopsis

double precision |=( geometry A , geometry B );

## Description

The `|=|` operator returns the 3D distance between two trajectories (See [ST\\_IsValidTrajectory](#)). This is the same as [ST\\_DistanceCPA](#) but as an operator it can be used for doing nearest neighbor searches using an N-dimensional index (requires PostgreSQL 9.5.0 or higher).

### Note

This operand will make use of ND GiST indexes that may be available on the geometries. It is different from other operators that use spatial indexes in that the spatial index is only used when the operator is in the ORDER BY clause.

### Note

Index only kicks in if one of the geometries is a constant (not in a subquery/cte). e.g. `'SRID=3005;LINESTRING(0 0 0,0 0 1)::geometry` instead of `a.geom`

Availability: 2.2.0. Index-supported only available for PostgreSQL 9.5+

## Examples

```
-- Save a literal query trajectory in a psql variable...
\set qt 'ST_AddMeasure(ST_MakeLine(ST_MakePointM(-350,300,0),ST_MakePointM(-410,490,0)) ↔
,10,20) '
-- Run the query !
SELECT track_id, dist FROM (
 SELECT track_id, ST_DistanceCPA(tr,:qt) dist
 FROM trajectories
 ORDER BY tr |=| :qt
 LIMIT 5
) foo;

## 8.8.29 <#>

<#> — Returns the 2D distance between A and B bounding boxes.

## Synopsis

```
double precision <#>(geometry A , geometry B);
```

## Description

The <#> operator returns distance between two floating point bounding boxes, possibly reading them from a spatial index (PostgreSQL 9.1+ required). Useful for doing nearest neighbor **approximate** distance ordering.

### Note

This operand will make use of any indexes that may be available on the geometries. It is different from other operators that use spatial indexes in that the spatial index is only used when the operator is in the ORDER BY clause.

### Note

Index only kicks in if one of the geometries is a constant e.g. ORDER BY (ST\_GeomFromText('POINT(1 2)') <#> geom) instead of g1.geom <#>.

Availability: 2.0.0 -- KNN only available for PostgreSQL 9.1+

## Examples

```

## 8.9 Spatial Relationships and Measurements

### 8.9.1 ST\_3DClosestPoint

**ST\_3DClosestPoint** — Returns the 3-dimensional point on g1 that is closest to g2. This is the first point of the 3D shortest line.

**Synopsis**

```
geometry ST_3DClosestPoint(geometry g1, geometry g2);
```

**Description**

Returns the 3-dimensional point on g1 that is closest to g2. This is the first point of the 3D shortest line. The 3D length of the 3D shortest line is the 3D distance.

This function supports 3d and will not drop the z-index.

This function supports Polyhedral surfaces.

Availability: 2.0.0

Changed: 2.2.0 - if 2 2D geometries are input, a 2D point is returned (instead of old behavior assuming 0 for missing Z). In case of 2D and 3D, Z is no longer assumed to be 0 for missing Z.

**Examples**

linestring and point -- both 3d and 2d closest point

```

SELECT ST_AsEWKT(ST_3DClosestPoint(line,pt)) AS cp3d_line_pt,
 ST_AsEWKT(ST_ClosestPoint(line,pt)) As cp2d_line_pt
FROM (SELECT 'POINT(100 100 30)::geometry As pt,
 'LINESTRING (20 80 20, 98 190 1, 110 180 3, 50 75 1000)::' AS ←
 geometry As line
) As foo;

**8.9.2 ST\_3DDistance**

**ST\_3DDistance** — For geometry type Returns the 3-dimensional cartesian minimum distance (based on spatial ref) between two geometries in projected units.

**Synopsis**

```
float ST_3DDistance(geometry g1, geometry g2);
```

**Description**

For geometry type returns the 3-dimensional minimum cartesian distance between two geometries in projected units (spatial ref units).

This function supports 3d and will not drop the z-index.

This function supports Polyhedral surfaces.

This method implements the SQL/MM specification. SQL-MM ?

This method is also provided by SFCGAL backend.

Availability: 2.0.0

Changed: 2.2.0 - In case of 2D and 3D, Z is no longer assumed to be 0 for missing Z.

## Examples

```
-- Geometry example - units in meters (SRID: 2163 US National Atlas Equal area) (3D point ←
 and line compared 2D point and line)
-- Note: currently no vertical datum support so Z is not transformed and assumed to be same ←
 units as final.

### 8.9.3 ST\_3DDWithin

**ST\_3DDWithin** — For 3d (z) geometry type Returns true if two geometries 3d distance is within number of units.

#### Synopsis

boolean **ST\_3DDWithin**(geometry g1, geometry g2, double precision distance\_of\_srid);

#### Description

For geometry type returns true if the 3d distance between two objects is within distance\_of\_srid specified projected units (spatial ref units).

This function supports 3d and will not drop the z-index.

This function supports Polyhedral surfaces.

This method implements the SQL/MM specification. SQL-MM ?

Availability: 2.0.0

### Examples

```
-- Geometry example - units in meters (SRID: 2163 US National Atlas Equal area) (3D point ←
 and line compared 2D point and line)
-- Note: currently no vertical datum support so Z is not transformed and assumed to be same ←
 units as final.

## 8.9.4 ST\_3DDFullyWithin

`ST_3DDFullyWithin` — Returns true if all of the 3D geometries are within the specified distance of one another.

### Synopsis

boolean `ST_3DDFullyWithin`(geometry g1, geometry g2, double precision distance);

### Description

Returns true if the 3D geometries are fully within the specified distance of one another. The distance is specified in units defined by the spatial reference system of the geometries. For this function to make sense, the source geometries must both be of the same coordinate projection, having the same SRID.

#### Note

This function call will automatically include a bounding box comparison that will make use of any indexes that are available on the geometries.

Availability: 2.0.0

This function supports 3d and will not drop the z-index.

This function supports Polyhedral surfaces.

## Examples

```
-- This compares the difference between fully within and distance within as well
-- as the distance fully within for the 2D footprint of the line/point vs. the 3d fully
 within
SELECT ST_3DDFullyWithin(geom_a, geom_b, 10) as D3DFullyWithin10, ST_3DDWithin(geom_a, ←
 geom_b, 10) as D3DWithin10,
ST_DFullyWithin(geom_a, geom_b, 20) as D2DFullyWithin20,
ST_3DDFullyWithin(geom_a, geom_b, 20) as D3DFullyWithin20 from
 (select ST_GeomFromEWKT('POINT(1 1 2)') as geom_a,
 ST_GeomFromEWKT('LINESTRING(1 5 2, 2 7 20, 1 9 100, 14 12 3)') as geom_b) t1;

## 8.9.5 ST\_3DIntersects

**ST\_3DIntersects** — Returns TRUE if the Geometries "spatially intersect" in 3d - only for points, linestrings, polygons, polyhedral surface (area). With SFCGAL backend enabled also supports TINS

### Synopsis

boolean **ST\_3DIntersects**( geometry geomA , geometry geomB );

### Description

Overlaps, Touches, Within all imply spatial intersection. If any of the aforementioned returns true, then the geometries also spatially intersect. Disjoint implies false for spatial intersection.

Availability: 2.0.0

#### Note

This function call will automatically include a bounding box comparison that will make use of any indexes that are available on the geometries.

#### Note

In order to take advantage of support for TINS, you need to enable the SFCGAL backend. This can be done at session time with: `set postgis.backend =sfcgal;` or at the database or system level. Database level can be done with `ALTER DATABASE gisdb SET postgis.backend =sfcgal;`.

This function supports 3d and will not drop the z-index.

This function supports Polyhedral surfaces.

This function supports Triangles and Triangulated Irregular Network Surfaces (TIN).

This method is also provided by SFCGAL backend.

This method implements the SQL/MM specification. SQL-MM 3: ?

### Geometry Examples

```
SELECT ST_3DIntersects(pt, line), ST_Intersects(pt,line)
 FROM (SELECT 'POINT(0 0 2)::geometry As pt,
 'LINESTRING (0 0 1, 0 2 3) '::geometry As line) As foo;
 st_3dintersects | st_intersects
-----+-----
 f | t
(1 row)
```

### TIN Examples

```
set postgis.backend = sfcgal;
SELECT ST_3DIntersects('TIN(((0 0,1 0,0 1,0 0))) '::geometry, 'POINT(.1 .1) '::geometry);
 st_3dintersects

 t
```

## 8.9.6 ST\_3DLongestLine

**ST\_3DLongestLine** — Returns the 3-dimensional longest line between two geometries

### Synopsis

```
geometry ST_3DLongestLine(geometry g1, geometry g2);
```

### Description

Returns the 3-dimensional longest line between two geometries. The function will only return the first longest line if more than one. The line returned will always start in g1 and end in g2. The 3D length of the line this function returns will always be the same as [ST\\_3DMaxDistance](#) returns for g1 and g2.

Availability: 2.0.0

Changed: 2.2.0 - if 2 2D geometries are input, a 2D point is returned (instead of old behavior assuming 0 for missing Z). In case of 2D and 3D, Z is no longer assumed to be 0 for missing Z.

This function supports 3d and will not drop the z-index.

This function supports Polyhedral surfaces.

### Examples

**linestring and point -- both 3d and 2d longest line**

```

## 8.9.8 ST\_3DShortestLine

`ST_3DShortestLine` — Returns the 3-dimensional shortest line between two geometries

### Synopsis

geometry **ST\_3DShortestLine**(geometry g1, geometry g2);

### Description

Returns the 3-dimensional shortest line between two geometries. The function will only return the first shortest line if more than one, that the function finds. If g1 and g2 intersects in just one point the function will return a line with both start and end in that intersection-point. If g1 and g2 are intersecting with more than one point the function will return a line with start and end in the same point but it can be any of the intersecting points. The line returned will always start in g1 and end in g2. The 3D length of the line this function returns will always be the same as [ST\\_3DDistance](#) returns for g1 and g2.

Availability: 2.0.0

Changed: 2.2.0 - if 2 2D geometries are input, a 2D point is returned (instead of old behavior assuming 0 for missing Z). In case of 2D and 3D, Z is no longer assumed to be 0 for missing Z.

This function supports 3d and will not drop the z-index.

This function supports Polyhedral surfaces.

**Examples**

```

**8.9.9 ST\_Area**

**ST\_Area** — Returns the area of the surface if it is a Polygon or MultiPolygon. For geometry, a 2D Cartesian area is determined with units specified by the SRID. For geography, area is determined on a curved surface with units in square meters.

**Synopsis**

```
float ST_Area(geometry g1);
float ST_Area(geography geog, boolean use_spheroid=true);
```

**Description**

Returns the area of the geometry if it is a Polygon or MultiPolygon. Return the area measurement of an ST\_Surface or ST\_MultiSurface value. For geometry, a 2D Cartesian area is determined with units specified by the SRID. For geography, by default area is determined on a spheroid with units in square meters. To measure around the faster but less accurate sphere, use ST\_Area(geog,false).

Enhanced: 2.0.0 - support for 2D polyhedral surfaces was introduced.

Enhanced: 2.2.0 - measurement on spheroid performed with GeographicLib for improved accuracy and robustness. Requires Proj >= 4.9.0 to take advantage of the new feature.

This method implements the [OpenGIS Simple Features Implementation Specification for SQL 1.1](#).

This method implements the SQL/MM specification. SQL-MM 3: 8.1.2, 9.5.3

This function supports Polyhedral surfaces.

**Note**

For polyhedral surfaces, only supports 2D polyhedral surfaces (not 2.5D). For 2.5D, may give a non-zero answer, but only for the faces that sit completely in XY plane.

This method is also provided by SFCGAL backend.

**Examples**

Return area in square feet for a plot of Massachusetts land and multiply by conversion to get square meters. Note this is in square feet because EPSG:2249 is Massachusetts State Plane Feet

```
SELECT ST_Area(the_geom) As sqft, ST_Area(the_geom)*POWER(0.3048,2) As sqm
FROM (SELECT
 ST_GeomFromText ('POLYGON((743238 2967416,743238 2967450,
 743265 2967450,743265.625 2967416,743238 2967416))',2249)) As foo(the_geom);
sqft | sqm
-----+-----
928.625 | 86.27208552
```

Return area square feet and transform to Massachusetts state plane meters (EPSG:26986) to get square meters. Note this is in square feet because 2249 is Massachusetts State Plane Feet and transformed area is in square meters since EPSG:26986 is state plane Massachusetts meters

```
SELECT ST_Area(the_geom) As sqft, ST_Area(ST_Transform(the_geom,26986)) As sqm
FROM (SELECT
 ST_GeomFromText ('POLYGON((743238 2967416,743238 2967450,
 743265 2967450,743265.625 2967416,743238 2967416))',2249)) As foo(the_geom);
sqft | sqm
-----+-----
928.625 | 86.2724304199219
```

Return area square feet and square meters using geography data type. Note that we transform to our geometry to geography (before you can do that make sure your geometry is in WGS 84 long lat 4326). Geography always measures in meters. This is just for demonstration to compare. Normally your table will be stored in geography data type already.

```
SELECT ST_Area(the_geog)/POWER(0.3048,2) As sqft_spheroid, ST_Area(the_geog,false)/POWER(←
 (0.3048,2) As sqft_sphere, ST_Area(the_geog) As sqm_spheroid
FROM (SELECT
 geography(
 ST_Transform(
 ST_GeomFromText ('POLYGON((743238 2967416,743238 2967450,743265 2967450,743265.625 ←
 2967416,743238 2967416))',
 2249
) ,4326
)
)
) As foo(the_geog);
sqft_spheroid | sqft_sphere | sqm_spheroid
-----+-----+-----
928.684403538925 | 927.049336105925 | 86.2776042893529

--if your data is in geography already
SELECT ST_Area(the_geog)/POWER(0.3048,2) As sqft, ST_Area(the_geog) As sqm
FROM somegeogtable;
```

### 8.9.10 ST\_Azimuth

**ST\_Azimuth** — Returns the north-based azimuth as the angle in radians measured clockwise from the vertical on pointA to pointB.

#### Synopsis

```
float ST_Azimuth(geometry pointA, geometry pointB);
float ST_Azimuth(geography pointA, geography pointB);
```

#### Description

Returns the azimuth in radians of the segment defined by the given point geometries, or NULL if the two points are coincident. The azimuth is angle is referenced from north, and is positive clockwise: North = 0; East =  $\pi/2$ ; South =  $\pi$ ; West =  $3\pi/2$ .

For the geography type, the forward azimuth is solved as part of the inverse geodesic problem.

The azimuth is mathematical concept defined as the angle between a reference plane and a point, with angular units in radians. Units can be converted to degrees using a built-in PostgreSQL function `degrees()`, as shown in the example.

Availability: 1.1.0

Enhanced: 2.0.0 support for geography was introduced.

Enhanced: 2.2.0 measurement on spheroid performed with GeographicLib for improved accuracy and robustness. Requires Proj  $\geq$  4.9.0 to take advantage of the new feature.

Azimuth is especially useful in conjunction with `ST_Translate` for shifting an object along its perpendicular axis. See [upgis\\_lineshift](#) [Plpgsqlfunctions PostGIS wiki section](#) for example of this.

### Examples

#### Geometry Azimuth in degrees

```
SELECT degrees(ST_Azimuth(ST_Point(25, 45), ST_Point(75, 100))) AS degA_B,
 degrees(ST_Azimuth(ST_Point(75, 100), ST_Point(25, 45))) AS degB_A;
```

dega_b	degb_a

### 8.9.11 ST\_Centroid

`ST_Centroid` — Returns the geometric center of a geometry.

## Synopsis

geometry **ST\_Centroid**(geometry g1);

## Description

Computes the geometric center of a geometry, or equivalently, the center of mass of the geometry as a POINT. For [MULTI]POINTS, this is computed as the arithmetic mean of the input coordinates. For [MULTI]LINESTRINGS, this is computed as the weighted length of each line segment. For [MULTI]POLYGONS, "weight" is thought in terms of area. If an empty geometry is supplied, an empty GEOMETRYCOLLECTION is returned. If NULL is supplied, NULL is returned. If CIRCULARSTRING or COMPOUNDCURVE are supplied, they are converted to linestring with CurveToLine first, then same than for LINESTRING

New in 2.3.0 : support CIRCULARSTRING and COMPOUNDCURVE (using CurveToLine)

The centroid is equal to the centroid of the set of component Geometries of highest dimension (since the lower-dimension geometries contribute zero "weight" to the centroid).

This method implements the [OpenGIS Simple Features Implementation Specification for SQL 1.1](#).

This method implements the SQL/MM specification. SQL-MM 3: 8.1.4, 9.5.5

## Examples

In each of the following illustrations, the blue dot represents the centroid of the source geometry.

```

SELECT ST_AsText(ST_Centroid('MULTIPOINT (-1 0, -1 2, -1 3, -1 4, -1 7, 0 1, 0 3, 1 1, 2 0, 6 0, 7 8, 9 8, 10 6)'));
 st_astext

POINT(2.30769230769231 3.30769230769231)
(1 row)

SELECT ST_AsText(ST_centroid(g))
FROM ST_GeomFromText ('CIRCULARSTRING(0 2, -1 1,0 0, 0.5 0, 1 0, 2 1, 1 2, 0.5 2, 0 2)') AS g ;

POINT(0.5 1)

SELECT ST_AsText(ST_centroid(g))
FROM ST_GeomFromText ('COMPOUNDCURVE(CIRCULARSTRING(0 2, -1 1,0 0),(0 0, 0.5 0, 1 0), CIRCULARSTRING(1 0, 2 1, 1 2),(1 2, 0.5 2, 0 2))') AS g;

POINT(0.5 1)

```

### 8.9.12 ST\_ClosestPoint

**ST\_ClosestPoint** — Returns the 2-dimensional point on g1 that is closest to g2. This is the first point of the shortest line.

#### Synopsis

geometry **ST\_ClosestPoint**(geometry g1, geometry g2);

**Description**

Returns the 2-dimensional point on g1 that is closest to g2. This is the first point of the shortest line.

**Note**

If you have a 3D Geometry, you may prefer to use [ST\\_3DClosestPoint](#).

Availability: 1.5.0

**Examples**

	
<p><i>Closest between point and linestring is the point itself, but closest point between a linestring and point is the point on line string that is closest.</i></p>	<p><i>closest point on polygon A to polygon B</i></p>
<pre>SELECT ST_AsText(ST_ClosestPoint(pt,line) ↔ ) AS cp_pt_line,       ST_AsText(ST_ClosestPoint(line,pt ↔ )) AS cp_line_pt FROM (SELECT 'POINT(100 100)::geometry ↔ As pt,         'LINESTRING (20 80, 98 ↔ 190, 110 180, 50 75 )::geometry As line ) As foo;</pre>	<pre>SELECT ST_AsText (           ST_ClosestPoint (             ST_GeomFromText (' ↔ POLYGON((175 150, 20 40, 50 60, 125 100, 175 150 ↔ ST_GeomFromText ('POINT(110 170)'), 20)           ) As ptwkt;</pre>
<pre>cp_pt_line   ↔ cp_line_pt</pre>	<pre>ptwkt ↔ POINT(140.752120669087 125.695053378061)</pre>

**8.9.13 ST\_ClusterDBSCAN**

`ST_ClusterDBSCAN` — Windowing function that returns integer id for the cluster each input geometry is in based on 2D implementation of Density-based spatial clustering of applications with noise (DBSCAN) algorithm.

**Synopsis**

integer `ST_ClusterDBSCAN`(geometry winset geom, float8 eps, integer minpoints);

**Description**

Returns cluster number for each input geometry, based on a 2D implementation of the [Density-based spatial clustering of applications with noise \(DBSCAN\)](#) algorithm. Unlike `ST_ClusterKMeans`, it does not require the number of clusters to be specified, but instead uses the desired distance (`eps`) and density(`minpoints`) parameters to construct each cluster.

An input geometry will be added to a cluster if it is either:

- A "core" geometry, that is within `eps` distance (Cartesian) of at least `minpoints` input geometries (including itself) or
- A "border" geometry, that is within `eps` distance of a core geometry.

Note that border geometries may be within `eps` distance of core geometries in more than one cluster; in this case, either assignment would be correct, and the border geometry will be arbitrarily assigned to one of the available clusters. In these cases, it is possible for a correct cluster to be generated with fewer than `minpoints` geometries. When assignment of a border geometry is ambiguous, repeated calls to `ST_ClusterDBSCAN` will produce identical results if an `ORDER BY` clause is included in the window definition, but cluster assignments may differ from other implementations of the same algorithm.

**Note**

Input geometries that do not meet the criteria to join any other cluster will be assigned a cluster number of NULL.

Availability: 2.3.0 - requires GEOS

**Examples**

Assigning a cluster number to each parcel point:

```
SELECT parcel_id, ST_ClusterDBSCAN(geom, eps := 0.5, minpoints := 5) over () AS cid
FROM parcels;
```

Combining parcels with the same cluster number into a single geometry. This uses named argument calling

```
SELECT cid, ST_Collect(geom) AS cluster_geom, array_agg(parcel_id) AS ids_in_cluster FROM (
 SELECT parcel_id, ST_ClusterDBSCAN(geom, eps := 0.5, minpoints := 5) over () AS cid, ↵
 geom
 FROM parcels) sq
GROUP BY cid;
```

**8.9.14 ST\_ClusterIntersecting**

`ST_ClusterIntersecting` — Aggregate. Returns an array with the connected components of a set of geometries

**Synopsis**

```
geometry[] ST_ClusterIntersecting(geometry set g);
```

**Description**

`ST_ClusterIntersecting` is an aggregate function that returns an array of `GeometryCollections`, where each `GeometryCollection` represents an interconnected set of geometries.

Availability: 2.2.0 - requires GEOS

**Examples**

```
WITH testdata AS
 (SELECT unnest(ARRAY['LINESTRING (0 0, 1 1)::geometry',
 'LINESTRING (5 5, 4 4)::geometry',
 'LINESTRING (6 6, 7 7)::geometry',
 'LINESTRING (0 0, -1 -1)::geometry',
 'POLYGON ((0 0, 4 0, 4 4, 0 4, 0 0))::geometry']) AS geom)

SELECT ST_AsText(unnest(ST_ClusterIntersecting(geom))) FROM testdata;

--result

st_astext

GEOMETRYCOLLECTION(LINESTRING(0 0,1 1),LINESTRING(5 5,4 4),LINESTRING(0 0,-1 -1),POLYGON((0 ←
 0,4 0,4 4,0 4,0 0)))

**8.9.15 ST\_ClusterKMeans**

`ST_ClusterKMeans` — Windowing function that returns integer id for the cluster each input geometry is in.

**Synopsis**

```
integer ST_ClusterKMeans(geometry winset geom, integer number_of_clusters);
```

## Description

Returns 2D distance based **k-means** cluster number for each input geometry. The distance used for clustering is the distance between the centroids of the geometries.

Availability: 2.3.0 - requires GEOS

## Examples

Generate dummy set of parcels for examples

```
CREATE TABLE parcels AS
SELECT lpad(row_number() over()::text,3,'0') As parcel_id, geom,
('{residential, commercial}'::text[])[1 + mod(row_number()OVER(),2)] As type
FROM
 ST_Subdivide(ST_Buffer('LINESTRING(40 100, 98 100, 100 150, 60 90)'::geometry,
 40, 'endcap=square'),12) As geom;
```

*Original Parcels*

```
-- Partitioning parcel clusters by type
SELECT ST_ClusterKMeans(geom,3) over (PARTITION BY type) AS cid, parcel_id, type
FROM parcels;
-- result
cid | parcel_id | type
-----+-----+-----
 1 | 005 | commercial
 1 | 003 | commercial
 2 | 007 | commercial
 0 | 001 | commercial
 1 | 004 | residential
 0 | 002 | residential
 2 | 006 | residential
(7 rows)
```

**8.9.17 ST\_Contains**

**ST\_Contains** — Returns true if and only if no points of B lie in the exterior of A, and at least one point of the interior of B lies in the interior of A.

**Synopsis**

```
boolean ST_Contains(geometry geomA, geometry geomB);
```

## Description

Geometry A contains Geometry B if and only if no points of B lie in the exterior of A, and at least one point of the interior of B lies in the interior of A. An important subtlety of this definition is that A does not contain its boundary, but A does contain itself. Contrast that to [ST\\_ContainsProperly](#) where geometry A does not Contain Properly itself.

Returns TRUE if geometry B is completely inside geometry A. For this function to make sense, the source geometries must both be of the same coordinate projection, having the same SRID. ST\_Contains is the inverse of ST\_Within. So ST\_Contains(A,B) implies ST\_Within(B,A) except in the case of invalid geometries where the result is always false regardless or not defined.

Performed by the GEOS module

Enhanced: 2.3.0 Enhancement to PIP short-circuit extended to support MultiPoints with few points. Prior versions only supported point in polygon.

### Important

Do not call with a GEOMETRYCOLLECTION as an argument

---

### Important

Do not use this function with invalid geometries. You will get unexpected results.

---

This function call will automatically include a bounding box comparison that will make use of any indexes that are available on the geometries. To avoid index use, use the function `_ST_Contains`.

NOTE: this is the "allowable" version that returns a boolean, not an integer.

This method implements the [OpenGIS Simple Features Implementation Specification for SQL 1.1](#). s2.1.1.2 // s2.1.13.3 - same as `within(geometry B, geometry A)`

This method implements the SQL/MM specification. SQL-MM 3: 5.1.31

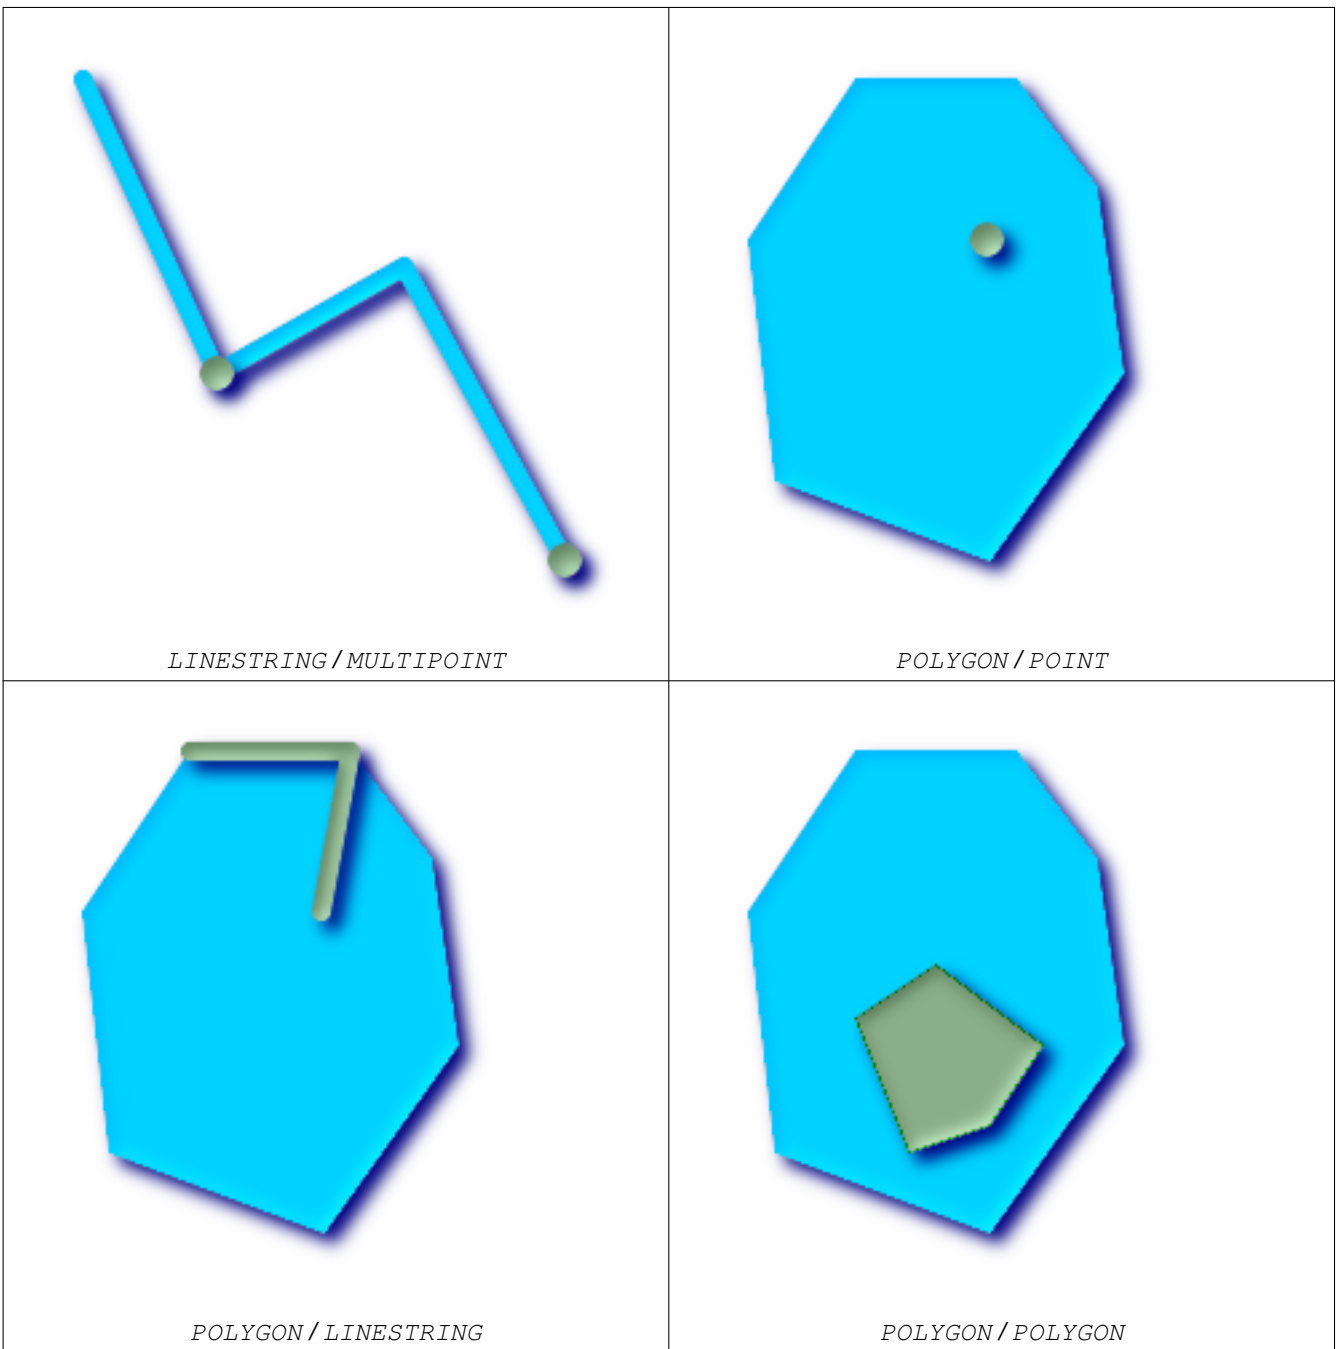

There are certain subtleties to ST\_Contains and ST\_Within that are not intuitively obvious. For details check out [Subtleties of OGC Covers, Contains, Within](#)

## Examples

The ST\_Contains predicate returns TRUE in all the following illustrations.

---

---

The `ST_Contains` predicate returns `FALSE` in all the following illustrations.

---

```
-- A circle within a circle
SELECT ST_Contains(smallc, bigc) As smallcontainsbig,
 ST_Contains(bigc,smallc) As bigcontainssmall,
 ST_Contains(bigc, ST_Union(smallc, bigc)) as bigcontainsunion,
 ST_Equals(bigc, ST_Union(smallc, bigc)) as bigisunion,
 ST_Covers(bigc, ST_ExteriorRing(bigc)) As bigcoversexterior,
 ST_Contains(bigc, ST_ExteriorRing(bigc)) As bigcontainsexterior
FROM (SELECT ST_Buffer(ST_GeomFromText('POINT(1 2)'), 10) As smallc,
 ST_Buffer(ST_GeomFromText('POINT(1 2)'), 20) As bigc) As foo;

-- Result
smallcontainsbig | bigcontainssmall | bigcontainsunion | bigisunion | bigcoversexterior | bigcontainsexterior
-----+-----+-----+-----+-----+-----
f | t | t | t | t | f

-- Example demonstrating difference between contains and contains properly
SELECT ST_GeometryType(geomA) As geomtype, ST_Contains(geomA,geomA) AS acontainsa, ST_ContainsProperly(geomA, geomA) AS acontainspropa,
 ST_Contains(geomA, ST_Boundary(geomA)) As acontainsba, ST_ContainsProperly(geomA, ST_Boundary(geomA)) As acontainspropba
FROM (VALUES (ST_Buffer(ST_Point(1,1), 5,1)),
 (ST_MakeLine(ST_Point(1,1), ST_Point(-1,-1))),
 (ST_Point(1,1))
) As foo(geomA);

geomtype | acontainsa | acontainspropa | acontainsba | acontainspropba
-----+-----+-----+-----+-----
ST_Polygon | t | f | f | f
ST_LineString | t | f | f | f
ST_Point | t | t | f | f
```

## See Also

## 8.9.18 ST\_ContainsProperly

`ST_ContainsProperly` — Returns true if B intersects the interior of A but not the boundary (or exterior). A does not contain properly itself, but does contain itself.

### Synopsis

```
boolean ST_ContainsProperly(geometry geomA, geometry geomB);
```

### Description

Returns true if B intersects the interior of A but not the boundary (or exterior).

A does not contain properly itself, but does contain itself.

Every point of the other geometry is a point of this geometry's interior. The DE-9IM Intersection Matrix for the two geometries matches [T\*\*FF\*FF\*] used in [ST\\_Relate](#)

---

#### Note

From JTS docs slightly reworded: The advantage to using this predicate over [ST\\_Contains](#) and [ST\\_Intersects](#) is that it can be computed efficiently, with no need to compute topology at individual points.

An example use case for this predicate is computing the intersections of a set of geometries with a large polygonal geometry. Since intersection is a fairly slow operation, it can be more efficient to use `containsProperly` to filter out test geometries which lie wholly inside the area. In these cases the intersection is known a priori to be exactly the original test geometry.

---

Availability: 1.4.0 - requires GEOS >= 3.1.0.

#### Important

Do not call with a `GEOMETRYCOLLECTION` as an argument

---

#### Important

Do not use this function with invalid geometries. You will get unexpected results.

---

This function call will automatically include a bounding box comparison that will make use of any indexes that are available on the geometries. To avoid index use, use the function `_ST_ContainsProperly`.

## Examples

---

```
--a circle within a circle
SELECT ST_ContainsProperly(smallc, bigc) As smallcontainspropbig,
ST_ContainsProperly(bigc,smallc) As bigcontainspropsmall,
ST_ContainsProperly(bigc, ST_Union(smallc, bigc)) as bigcontainspropunion,
ST_Equals(bigc, ST_Union(smallc, bigc)) as bigisunion,
ST_Covers(bigc, ST_ExteriorRing(bigc)) As bigcoversexterior,
ST_ContainsProperly(bigc, ST_ExteriorRing(bigc)) As bigcontainsexterior
FROM (SELECT ST_Buffer(ST_GeomFromText('POINT(1 2)'), 10) As smallc,
ST_Buffer(ST_GeomFromText('POINT(1 2)'), 20) As bigc) As foo;
--Result
smallcontainspropbig | bigcontainspropsmall | bigcontainspropunion | bigisunion | ↔
bigcoversexterior | bigcontainsexterior
```

---

f	t	f	t	t ↔
	f

## 8.9.21 ST\_Crosses

`ST_Crosses` — Returns `TRUE` if the supplied geometries have some, but not all, interior points in common.

### Synopsis

boolean `ST_Crosses`(geometry g1, geometry g2);

### Description

`ST_Crosses` takes two geometry objects and returns `TRUE` if their intersection "spatially cross", that is, the geometries have some, but not all interior points in common. The intersection of the interiors of the geometries must not be the empty set and must have a dimensionality less than the maximum dimension of the two input geometries. Additionally, the intersection of the two geometries must not equal either of the source geometries. Otherwise, it returns `FALSE`.

In mathematical terms, this is expressed as:

$$a.Crosses(b) \Leftrightarrow (dim(I(a) \cap I(b)) < max(dim(I(a)), dim(I(b)))) \wedge (a \cap b \neq a) \wedge (a \cap b \neq b)$$

The DE-9IM Intersection Matrix for the two geometries is:

- T\*T\*\*\*\*\* (for Point/Line, Point/Area, and Line/Area situations)
- T\*\*\*\*\*T\*\* (for Line/Point, Area/Point, and Area/Line situations)
- 0\*\*\*\*\* (for Line/Line situations)

For any other combination of dimensions this predicate returns false.

The OpenGIS Simple Features Specification defines this predicate only for Point/Line, Point/Area, Line/Line, and Line/Area situations. JTS / GEOS extends the definition to apply to Line/Point, Area/Point and Area/Line situations as well. This makes the relation symmetric.

#### Important

Do not call with a `GEOMETRYCOLLECTION` as an argument

---

#### Note

This function call will automatically include a bounding box comparison that will make use of any indexes that are available on the geometries.

---

This method implements the [OpenGIS Simple Features Implementation Specification for SQL 1.1](#). s2.1.13.3

This method implements the SQL/MM specification. SQL-MM 3: 5.1.29

---

**Examples**

The following illustrations all return TRUE.

Consider a situation where a user has two tables: a table of roads and a table of highways.

---

```
CREATE TABLE roads (
 id serial NOT NULL,
 the_geom geometry,
 CONSTRAINT roads_pkey PRIMARY KEY (↵
 road_id)
);
```

```
CREATE TABLE highways (
 id serial NOT NULL,
 the_gem geometry,
 CONSTRAINT roads_pkey PRIMARY KEY (↵
 road_id)
);
```

To determine a list of roads that cross a highway, use a query similiar to:

```
SELECT roads.id
FROM roads, highways
WHERE ST_Crosses(roads.the_geom, highways.the_geom);
```

### 8.9.22 ST\_LineCrossingDirection

**ST\_LineCrossingDirection** — Given 2 linestrings, returns a number between -3 and 3 denoting what kind of crossing behavior. 0 is no crossing.

#### Synopsis

integer **ST\_LineCrossingDirection**(geometry linestringA, geometry linestringB);

#### Description

Given 2 linestrings, returns a number between -3 and 3 denoting what kind of crossing behavior. 0 is no crossing. This is only supported for `LINESTRING`

Definition of integer constants is as follows:

- 0: LINE NO CROSS
- -1: LINE CROSS LEFT
- 1: LINE CROSS RIGHT
- -2: LINE MULTICROSS END LEFT
- 2: LINE MULTICROSS END RIGHT
- -3: LINE MULTICROSS END SAME FIRST LEFT
- 3: LINE MULTICROSS END SAME FIRST RIGHT

Availability: 1.4

**8.9.23 ST\_Disjoint**

ST\_Disjoint — Returns TRUE if the Geometries do not "spatially intersect" - if they do not share any space together.

**Synopsis**

boolean **ST\_Disjoint**( geometry A , geometry B );

## Description

Overlaps, Touches, Within all imply geometries are not spatially disjoint. If any of the aforementioned returns true, then the geometries are not spatially disjoint. Disjoint implies false for spatial intersection.

### Important

Do not call with a `GEOMETRYCOLLECTION` as an argument

Performed by the GEOS module

### Note

This function call does not use indexes

### Note

NOTE: this is the "allowable" version that returns a boolean, not an integer.

This method implements the [OpenGIS Simple Features Implementation Specification for SQL 1.1](#). s2.1.1.2 //s2.1.13.3 - a.Relate(b, 'FF\*FF\*\*\*\*')

This method implements the SQL/MM specification. SQL-MM 3: 5.1.26

## Examples

```
SELECT ST_Disjoint('POINT(0 0)::geometry, 'LINESTRING (2 0, 0 2) '::geometry);
st_disjoint

t
(1 row)
SELECT ST_Disjoint('POINT(0 0)::geometry, 'LINESTRING (0 0, 0 2) '::geometry);
st_disjoint

f
(1 row)
```

## 8.9.24 ST\_Distance

`ST_Distance` — For geometry type Returns the 2D Cartesian distance between two geometries in projected units (based on spatial ref). For geography type defaults to return minimum geodesic distance between two geographies in meters.

## Synopsis

```
float ST_Distance(geometry g1, geometry g2);
float ST_Distance(geography gg1, geography gg2);
float ST_Distance(geography gg1, geography gg2, boolean use_spheroid);
```

## Description

For geometry type returns the minimum 2D Cartesian distance between two geometries in projected units (spatial ref units). For geography type defaults to return the minimum geodesic distance between two geographies in meters. If `use_spheroid` is false, a faster sphere calculation is used instead of a spheroid.

This method implements the [OpenGIS Simple Features Implementation Specification for SQL 1.1](#).

This method implements the SQL/MM specification. SQL-MM 3: 5.1.23

This method supports Circular Strings and Curves

This method is also provided by SFCGAL backend.

Availability: 1.5.0 geography support was introduced in 1.5. Speed improvements for planar to better handle large or many vertex geometries

Enhanced: 2.1.0 improved speed for geography. See [Making Geography faster](#) for details.

Enhanced: 2.1.0 - support for curved geometries was introduced.

Enhanced: 2.2.0 - measurement on spheroid performed with GeographicLib for improved accuracy and robustness. Requires Proj >= 4.9.0 to take advantage of the new feature.

## Basic Geometry Examples

```
--Geometry example - units in planar degrees 4326 is WGS 84 long lat unit=degrees
SELECT ST_Distance(
 ST_GeomFromText('POINT(-72.1235 42.3521)',4326),
 ST_GeomFromText('LINESTRING(-72.1260 42.45, -72.123 42.1546)', 4326)
);
st_distance

0.00150567726382282

### 8.9.25 ST\_MinimumClearance

`ST_MinimumClearance` — Returns the minimum clearance of a geometry, a measure of a geometry's robustness.

#### Synopsis

```
float ST_MinimumClearance(geometry g);
```

#### Description

It is not uncommon to have a geometry that, while meeting the criteria for validity according to `ST_IsValid` (polygons) or `ST_IsSimple` (lines), would become invalid if one of the vertices moved by a slight distance, as can happen during conversion to text-based formats (such as WKT, KML, GML GeoJSON), or binary formats that do not use double-precision floating point coordinates (MapInfo TAB).

A geometry's "minimum clearance" is the smallest distance by which a vertex of the geometry could be moved to produce an invalid geometry. It can be thought of as a quantitative measure of a geometry's robustness, where increasing values of minimum clearance indicate increasing robustness.

If a geometry has a minimum clearance of  $\epsilon$ , it can be said that:

- No two distinct vertices in the geometry are separated by less than  $\epsilon$ .
- No vertex is closer than  $\epsilon$  to a line segment of which it is not an endpoint.

If no minimum clearance exists for a geometry (for example, a single point, or a multipoint whose points are identical), then `ST_MinimumClearance` will return Infinity.

Availability: 2.3.0 - requires GEOS  $\geq$  3.6.0

## Examples

```
SELECT ST_MinimumClearance('POLYGON ((0 0, 1 0, 1 1, 0.5 3.2e-4, 0 0))');
st_minimumclearance

0.00032
```

## See Also

[ST\\_MinimumClearanceLine](#)

### 8.9.26 ST\_MinimumClearanceLine

`ST_MinimumClearanceLine` — Returns the two-point `LineString` spanning a geometry's minimum clearance.

## Synopsis

Geometry `ST_MinimumClearanceLine`(geometry g);

## Description

Returns the two-point `LineString` spanning a geometry's minimum clearance. If the geometry does not have a minimum clearance, `LINestring EMPTY` will be returned.

Availability: 2.3.0 - requires GEOS >= 3.6.0

## Examples

```
SELECT ST_AsText(ST_MinimumClearanceLine('POLYGON ((0 0, 1 0, 1 1, 0.5 3.2e-4, 0 0))'));
st_astext

LINestring(0.5 0.00032,0.5 0)
```

## See Also

[ST\\_MinimumClearance](#)

### 8.9.27 ST\_HausdorffDistance

`ST_HausdorffDistance` — Returns the Hausdorff distance between two geometries. Basically a measure of how similar or dissimilar 2 geometries are. Units are in the units of the spatial reference system of the geometries.

## Synopsis

float `ST_HausdorffDistance`(geometry g1, geometry g2);  
float `ST_HausdorffDistance`(geometry g1, geometry g2, float densifyFrac);

## Description

Implements algorithm for computing a distance metric which can be thought of as the "Discrete Hausdorff Distance". This is the Hausdorff distance restricted to discrete points for one of the geometries. [Wikipedia article on Hausdorff distance](#) [Martin Davis note on how Hausdorff Distance calculation was used to prove correctness of the CascadePolygonUnion approach](#).

When `densifyFrac` is specified, this function performs a segment densification before computing the discrete hausdorff distance. The `densifyFrac` parameter sets the fraction by which to densify each segment. Each segment will be split into a number of equal-length subsegments, whose fraction of the total length is closest to the given fraction.

### Note

The current implementation supports only vertices as the discrete locations. This could be extended to allow an arbitrary density of points to be used.

### Note

This algorithm is NOT equivalent to the standard Hausdorff distance. However, it computes an approximation that is correct for a large subset of useful cases. One important part of this subset is Linestrings that are roughly parallel to each other, and roughly equal in length. This is a useful metric for line matching.

Availability: 1.5.0 - requires GEOS >= 3.2.0

## Examples

For each building, find the parcel that best represents it. First we require the parcel intersect with the geometry. `DISTINCT ON` guarantees we get each building listed only once, the `ORDER BY .. ST_HausdorffDistance` gives us a preference of parcel that is most similar to the building.

```
SELECT DISTINCT ON(buildings.gid) buildings.gid, parcels.parcel_id
FROM buildings INNER JOIN parcels ON ST_Intersects(buildings.geom, parcels.geom)
ORDER BY buildings.gid, ST_HausdorffDistance(buildings.geom, parcels.geom);
```

```
postgis=# SELECT ST_HausdorffDistance(
 'LINESTRING (0 0, 2 0)::geometry,
 'MULTIPOINT (0 1, 1 0, 2 1)::geometry);
st_hausdorffdistance

1
(1 row)
```

```
postgis=# SELECT st_hausdorffdistance('LINESTRING (130 0, 0 0, 0 150)::geometry, ' ↔
 LINESTRING (10 10, 10 150, 130 10)::geometry, 0.5);
st_hausdorffdistance

70
(1 row)
```

### 8.9.28 ST\_MaxDistance

`ST_MaxDistance` — Returns the 2-dimensional largest distance between two geometries in projected units.

#### Synopsis

```
float ST_MaxDistance(geometry g1, geometry g2);
```

## Description

### Note

Returns the 2-dimensional maximum distance between two geometries in projected units. If g1 and g2 is the same geometry the function will return the distance between the two vertices most far from each other in that geometry.

Availability: 1.5.0

## Examples

Basic furthest distance the point is to any part of the line

```
postgis=# SELECT ST_MaxDistance('POINT(0 0)::geometry, 'LINESTRING (2 0, 0 2)'::geometry ←
);
 st_maxdistance

2
(1 row)

postgis=# SELECT ST_MaxDistance('POINT(0 0)::geometry, 'LINESTRING (2 2, 2 2)'::geometry ←
);
 st_maxdistance

2.82842712474619
(1 row)
```

## See Also

## 8.9.29 ST\_DistanceSphere

**ST\_DistanceSphere** — Returns minimum distance in meters between two lon/lat geometries. Uses a spherical earth and radius derived from the spheroid defined by the SRID. Faster than **ST\_DistanceSpheroid** [ST\\_DistanceSpheroid](#), but less accurate. PostGIS versions prior to 1.5 only implemented for points.

### Synopsis

```
float ST_DistanceSphere(geometry geom1lonlatA, geometry geom1lonlatB);
```

### Description

Returns minimum distance in meters between two lon/lat points. Uses a spherical earth and radius derived from the spheroid defined by the SRID. Faster than [ST\\_DistanceSpheroid](#), but less accurate. PostGIS Versions prior to 1.5 only implemented for points.

Availability: 1.5 - support for other geometry types besides points was introduced. Prior versions only work with points.

Changed: 2.2.0 In prior versions this used to be called `ST_Distance_Sphere`

## Examples

```
SELECT round(CAST(ST_DistanceSphere(ST_Centroid(the_geom), ST_GeomFromText('POINT(-118 38) ←
',4326)) As numeric),2) As dist_meters,
round(CAST(ST_Distance(ST_Transform(ST_Centroid(the_geom),32611),
ST_Transform(ST_GeomFromText('POINT(-118 38)', 4326),32611)) As numeric),2) As ←
dist_utm11_meters,
round(CAST(ST_Distance(ST_Centroid(the_geom), ST_GeomFromText('POINT(-118 38)', 4326)) As ←
numeric),5) As dist_degrees,
round(CAST(ST_Distance(ST_Transform(the_geom,32611),
ST_Transform(ST_GeomFromText('POINT(-118 38)', 4326),32611)) As numeric),2) As ←
min_dist_line_point_meters
FROM
(SELECT ST_GeomFromText('LINESTRING(-118.584 38.374,-118.583 38.5)', 4326) As the_geom) ←
as foo;
dist_meters | dist_utm11_meters | dist_degrees | min_dist_line_point_meters
-----+-----+-----+-----

### 8.9.30 ST\_DistanceSpheroid

**ST\_DistanceSpheroid** — Returns the minimum distance between two lon/lat geometries given a particular spheroid. PostGIS versions prior to 1.5 only support points.

#### Synopsis

```
float ST_DistanceSpheroid(geometry geomlonlatA, geometry geomlonlatB, spheroid measurement_spheroid);
```

#### Description

Returns minimum distance in meters between two lon/lat geometries given a particular spheroid. See the explanation of spheroids given for [ST\\_LengthSpheroid](#). PostGIS version prior to 1.5 only support points.

#### Note

This function currently does not look at the SRID of a geometry and will always assume its represented in the coordinates of the passed in spheroid. Prior versions of this function only support points.

Availability: 1.5 - support for other geometry types besides points was introduced. Prior versions only work with points.

Changed: 2.2.0 In prior versions this used to be called `ST_Distance_Spheroid`

## Examples

```
SELECT round(CAST(
ST_DistanceSpheroid(ST_Centroid(the_geom), ST_GeomFromText('POINT(-118 38)',4326), ' ←
SPHEROID["WGS 84",6378137,298.257223563]')
As numeric),2) As dist_meters_spheroid,
```

```

round(CAST(ST_DistanceSphere(ST_Centroid(the_geom), ST_GeomFromText('POINT(-118 38) ←
',4326)) As numeric),2) As dist_meters_sphere,
round(CAST(ST_Distance(ST_Transform(ST_Centroid(the_geom),32611),
ST_Transform(ST_GeomFromText('POINT(-118 38)', 4326),32611)) As numeric),2) As ←
dist_utm11_meters
FROM
(SELECT ST_GeomFromText('LINESTRING(-118.584 38.374,-118.583 38.5)', 4326) As the_geom) ←
as foo;
dist_meters_spheroid | dist_meters_sphere | dist_utm11_meters
-----+-----+-----
70454.92 | 70424.47 | 70438.00

```

**See Also**

[ST\\_Distance](#), [ST\\_DistanceSphere](#)

**8.9.31 ST\_DFullyWithin**

`ST_DFullyWithin` — Returns true if all of the geometries are within the specified distance of one another

**Synopsis**

boolean `ST_DFullyWithin`(geometry g1, geometry g2, double precision distance);

**Description**

Returns true if the geometries is fully within the specified distance of one another. The distance is specified in units defined by the spatial reference system of the geometries. For this function to make sense, the source geometries must both be of the same coordinate projection, having the same SRID.

**Note**

This function call will automatically include a bounding box comparison that will make use of any indexes that are available on the geometries.

Availability: 1.5.0

**Examples**

```

postgis=# SELECT ST_DFullyWithin(geom_a, geom_b, 10) as DFullyWithin10, ST_DWithin(geom_a, ←
geom_b, 10) as DWithin10, ST_DFullyWithin(geom_a, geom_b, 20) as DFullyWithin20 from
(select ST_GeomFromText('POINT(1 1)') as geom_a,ST_GeomFromText('LINESTRING(1 5, 2 7, 1 ←
9, 14 12)') as geom_b) t1;

```

```

DFullyWithin10 | DWithin10 | DFullyWithin20 |
-----+-----+-----+
f | t | t |

```

**See Also**

[ST\\_MaxDistance](#), [ST\\_DWithin](#)

### 8.9.32 ST\_DWithin

**ST\_DWithin** — Returns true if the geometries are within the specified distance of one another. For geometry units are in those of spatial reference and For geography units are in meters and measurement is defaulted to use\_spheroid=true (measure around spheroid), for faster check, use\_spheroid=false to measure along sphere.

#### Synopsis

```
boolean ST_DWithin(geometry g1, geometry g2, double precision distance_of_srid);
boolean ST_DWithin(geography gg1, geography gg2, double precision distance_meters);
boolean ST_DWithin(geography gg1, geography gg2, double precision distance_meters, boolean use_spheroid);
```

#### Description

Returns true if the geometries are within the specified distance of one another.

For Geometries: The distance is specified in units defined by the spatial reference system of the geometries. For this function to make sense, the source geometries must both be of the same coordinate projection, having the same SRID.

For geography units are in meters and measurement is defaulted to use\_spheroid=true, for faster check, use\_spheroid=false to measure along sphere.

#### Note

This function call will automatically include a bounding box comparison that will make use of any indexes that are available on the geometries.

#### Note

Prior to 1.3, ST\_Expand was commonly used in conjunction with && and ST\_Distance to achieve the same effect and in pre-1.3.4 this function was basically short-hand for that construct. From 1.3.4, ST\_DWithin uses a more short-circuit distance function which should make it more efficient than prior versions for larger buffer regions.

#### Note

Use ST\_3DDWithin if you have 3D geometries.

This method implements the [OpenGIS Simple Features Implementation Specification for SQL 1.1](#).

Availability: 1.5.0 support for geography was introduced

Enhanced: 2.1.0 improved speed for geography. See [Making Geography faster](#) for details.

Enhanced: 2.1.0 support for curved geometries was introduced.

#### Examples

```
--Find the nearest hospital to each school
--that is within 3000 units of the school.
-- We do an ST_DWithin search to utilize indexes to limit our search list
-- that the non-indexable ST_Distance needs to process
--If the units of the spatial reference is meters then units would be meters
SELECT DISTINCT ON (s.gid) s.gid, s.school_name, s.the_geom, h.hospital_name
```

```

FROM schools s
 LEFT JOIN hospitals h ON ST_DWithin(s.the_geom, h.the_geom, 3000)
ORDER BY s.gid, ST_Distance(s.the_geom, h.the_geom);

--The schools with no close hospitals
--Find all schools with no hospital within 3000 units
--away from the school. Units is in units of spatial ref (e.g. meters, feet, degrees)
SELECT s.gid, s.school_name
 FROM schools s
 LEFT JOIN hospitals h ON ST_DWithin(s.the_geom, h.the_geom, 3000)
 WHERE h.gid IS NULL;

```

**See Also**

[ST\\_Distance](#), [ST\\_Expand](#)

**8.9.33 ST\_Equals**

**ST\_Equals** — Returns true if the given geometries represent the same geometry. Directionality is ignored.

**Synopsis**

boolean **ST\_Equals**(geometry A, geometry B);

**Description**

Returns TRUE if the given Geometries are "spatially equal". Use this for a 'better' answer than '='. Note by spatially equal we mean `ST_Within(A,B) = true` and `ST_Within(B,A) = true` and also mean ordering of points can be different but represent the same geometry structure. To verify the order of points is consistent, use `ST_OrderingEquals` (it must be noted `ST_OrderingEquals` is a little more stringent than simply verifying order of points are the same).

**Important**

This function will return false if either geometry is invalid except in the case where they are binary equal.

---

This method implements the [OpenGIS Simple Features Implementation Specification for SQL 1.1](#). s2.1.1.2

This method implements the SQL/MM specification. SQL-MM 3: 5.1.24

Changed: 2.2.0 Returns true even for invalid geometries if they are binary equal

**Examples**

```

SELECT ST_Equals(ST_GeomFromText('LINESTRING(0 0, 10 10)'),
 ST_GeomFromText('LINESTRING(0 0, 5 5, 10 10)'));
 st_equals

 t
(1 row)

SELECT ST_Equals(ST_Reverse(ST_GeomFromText('LINESTRING(0 0, 10 10)'),

```

---

```
ST_GeomFromText('LINESTRING(0 0, 5 5, 10 10)');
st_equals

t
(1 row)
```

## 8.9.34 ST\_GeometricMedian

`ST_GeometricMedian` — Returns the geometric median of a `MultiPoint`.

### Synopsis

geometry **ST\_GeometricMedian** ( geometry g , float8 tolerance , int max\_iter , boolean fail\_if\_not\_converged );

### Description

Computes the approximate geometric median of a `MultiPoint` geometry using the Weiszfeld algorithm. The geometric median provides a centrality measure that is less sensitive to outlier points than the centroid. The algorithm will iterate until the distance change between successive iterations is less than the supplied `tolerance` parameter. If this condition has not been met after `max_iterations` iterations, the function will produce an error and exit, unless `fail_if_not_converged` is set to false. If a tolerance value is not provided, a default tolerance value will be calculated based on the extent of the input geometry.

Availability: 2.3.0

This function supports 3d and will not drop the z-index.

### Examples

Comparison of the centroid (turquoise point) and geometric median (red point) of a four-point `MultiPoint` (yellow points).

```

WITH test AS (
SELECT 'MULTIPOINT((0 0), (1 1), (2 2), (200 200))'::geometry geom)
SELECT
 ST_AsText(ST_Centroid(geom)) centroid,
 ST_AsText(ST_GeometricMedian(geom)) median
FROM test;
 centroid | median
-----+-----
 POINT(50.75 50.75) | POINT(1.9761550281255 1.9761550281255)
(1 row)

```

**See Also**[ST\\_Centroid](#)**8.9.35 ST\_HasArc**

**ST\_HasArc** — Returns true if a geometry or geometry collection contains a circular string

**Synopsis**

boolean **ST\_HasArc**(geometry geomA);

**Description**

Returns true if a geometry or geometry collection contains a circular string

Availability: 1.2.3?

This function supports 3d and will not drop the z-index.

This method supports Circular Strings and Curves

**Examples**

```

SELECT ST_HasArc(ST_Collect('LINESTRING(1 2, 3 4, 5 6)', 'CIRCULARSTRING(1 1, 2 3, 4 5, 6 ←
7, 5 6)'));
 st_hasarc

 t

```

**See Also**[ST\\_CurveToLine](#), [ST\\_LineToCurve](#)**8.9.36 ST\_Intersects**

**ST\_Intersects** — Returns TRUE if the Geometries/Geography "spatially intersect in 2D" - (share any portion of space) and FALSE if they don't (they are Disjoint). For geography -- tolerance is 0.00001 meters (so any points that close are considered to intersect)

## Synopsis

```
boolean ST_Intersects(geometry geomA , geometry geomB);
boolean ST_Intersects(geography geogA , geography geogB);
```

## Description

If a geometry or geography shares any portion of space then they intersect. For geography -- tolerance is 0.00001 meters (so any points that are close are considered to intersect)

Overlaps, Touches, Within all imply spatial intersection. If any of the aforementioned returns true, then the geometries also spatially intersect. Disjoint implies false for spatial intersection.

### Important

Do not call with a `GEOMETRYCOLLECTION` as an argument for geometry version. The geography version supports `GEOMETRYCOLLECTION` since its a thin wrapper around distance implementation.

Enhanced: 2.3.0 Enhancement to PIP short-circuit extended to support MultiPoints with few points. Prior versions only supported point in polygon.

Performed by the GEOS module (for geometry), geography is native

Availability: 1.5 support for geography was introduced.

### Note

This function call will automatically include a bounding box comparison that will make use of any indexes that are available on the geometries.

### Note

For geography, this function has a distance tolerance of about 0.00001 meters and uses the sphere rather than spheroid calculation.

### Note

NOTE: this is the "allowable" version that returns a boolean, not an integer.

This method implements the [OpenGIS Simple Features Implementation Specification for SQL 1.1](#). s2.1.1.2 //s2.1.13.3 - `ST_Intersects(g1, g2 ) --> Not (ST_Disjoint(g1, g2 ))`

This method implements the SQL/MM specification. SQL-MM 3: 5.1.27

This method is also provided by SFCGAL backend.

## Geometry Examples

```
SELECT ST_Intersects('POINT(0 0)::geometry, 'LINESTRING (2 0, 0 2) '::geometry);
st_intersects

f
(1 row)
SELECT ST_Intersects('POINT(0 0)::geometry, 'LINESTRING (0 0, 0 2) '::geometry);
st_intersects

t
(1 row)
```

## Geography Examples

```
SELECT ST_Intersects (
 ST_GeographyFromText ('SRID=4326;LINESTRING(-43.23456 72.4567,-43.23456 72.4568)'),
 ST_GeographyFromText ('SRID=4326;POINT(-43.23456 72.4567772)')
);

st_intersects

t
```

### 8.9.37 ST\_Length

**ST\_Length** — Returns the 2D length of the geometry if it is a LineString or MultiLineString. geometry are in units of spatial reference and geography are in meters (default spheroid)

#### Synopsis

```
float ST_Length(geometry a_2dlinestring);
float ST_Length(geography geog, boolean use_spheroid=true);
```

#### Description

For geometry: Returns the 2D Cartesian length of the geometry if it is a LineString, MultiLineString, ST\_Curve, ST\_MultiCurve. 0 is returned for areal geometries. For areal geometries use [ST\\_Perimeter](#). For geometry types, units for length measures are specified by the spatial reference system of the geometry.

For geography types, the calculations are performed using the inverse geodesic problem, where length units are in meters. If PostGIS is compiled with PROJ version 4.8.0 or later, the spheroid is specified by the SRID, otherwise it is exclusive to WGS84. If `use_spheroid=false`, then calculations will approximate a sphere instead of a spheroid.

Currently for geometry this is an alias for `ST_Length2D`, but this may change to support higher dimensions.

#### Warning

Changed: 2.0.0 Breaking change -- in prior versions applying this to a MULTI/POLYGON of type geography would give you the perimeter of the POLYGON/MULTIPOLYGON. In 2.0.0 this was changed to return 0 to be in line with geometry behavior. Please use `ST_Perimeter` if you want the perimeter of a polygon

**Note**

For geography measurement defaults spheroid measurement. To use the faster less accurate sphere use `ST_Length(gg,false)`;

This method implements the [OpenGIS Simple Features Implementation Specification for SQL 1.1](#). s2.1.5.1

This method implements the SQL/MM specification. SQL-MM 3: 7.1.2, 9.3.4

Availability: 1.5.0 geography support was introduced in 1.5.

This method is also provided by SFCGAL backend.

**Geometry Examples**

Return length in feet for line string. Note this is in feet because EPSG:2249 is Massachusetts State Plane Feet

```
SELECT ST_Length(ST_GeomFromText('LINESTRING(743238 2967416,743238 2967450,743265 2967450,743265.625 2967416,743238 2967416)',2249));
st_length

122.630744000095

--Transforming WGS 84 LineString to Massachusetts state plane meters
SELECT ST_Length(
 ST_Transform(
 ST_GeomFromEWKT('SRID=4326;LINESTRING(-72.1260 42.45, -72.1240 42.45666, -72.123 42.1546)'),
 26986
)
);
st_length

34309.4563576191
```

**Geography Examples**

Return length of WGS 84 geography line

```
-- default calculation is using a sphere rather than spheroid
SELECT ST_Length(the_geog) As length_spheroid, ST_Length(the_geog,false) As length_sphere
FROM (SELECT ST_GeographyFromText(
'SRID=4326;LINESTRING(-72.1260 42.45, -72.1240 42.45666, -72.123 42.1546)') As the_geog)
As foo;
length_spheroid | length_sphere
-----+-----
34310.5703627288 | 34346.2060960742
```

### 8.9.38 ST\_Length2D

`ST_Length2D` — Returns the 2-dimensional length of the geometry if it is a linestring or multi-linestring. This is an alias for `ST_Length`

#### Synopsis

```
float ST_Length2D(geometry a_2dlinestring);
```

#### Description

Returns the 2-dimensional length of the geometry if it is a linestring or multi-linestring. This is an alias for `ST_Length`

#### See Also

[ST\\_Length](#), [ST\\_3DLength](#)

### 8.9.39 ST\_3DLength

`ST_3DLength` — Returns the 3-dimensional or 2-dimensional length of the geometry if it is a linestring or multi-linestring.

#### Synopsis

```
float ST_3DLength(geometry a_3dlinestring);
```

#### Description

Returns the 3-dimensional or 2-dimensional length of the geometry if it is a linestring or multi-linestring. For 2-d lines it will just return the 2-d length (same as `ST_Length` and `ST_Length2D`)

This function supports 3d and will not drop the z-index.

Changed: 2.0.0 In prior versions this used to be called `ST_Length3D`

#### Examples

Return length in feet for a 3D cable. Note this is in feet because EPSG:2249 is Massachusetts State Plane Feet

```
SELECT ST_3DLength(ST_GeomFromText('LINESTRING(743238 2967416 1,743238 2967450 1,743265 ←
 2967450 3,
743265.625 2967416 3,743238 2967416 3)',2249));
ST_3DLength

122.704716741457
```

#### See Also

## 8.9.40 ST\_LengthSpheroid

**ST\_LengthSpheroid** — Calculates the 2D or 3D length/perimeter of a geometry on an ellipsoid. This is useful if the coordinates of the geometry are in longitude/latitude and a length is desired without reprojection.

### Synopsis

```
float ST_LengthSpheroid(geometry a_geometry, spheroid a_spheroid);
```

### Description

Calculates the length/perimeter of a geometry on an ellipsoid. This is useful if the coordinates of the geometry are in longitude/latitude and a length is desired without reprojection. The ellipsoid is a separate database type and can be constructed as follows:

```
SPHEROID [<NAME>, <SEMI-MAJOR AXIS>, <INVERSE FLATTENING>]
```

```
SPHEROID ["GRS_1980", 6378137, 298.257222101]
```

Availability: 1.2.2

Changed: 2.2.0 In prior versions this used to be called ST\_Length\_Spheroid and used to have a ST\_3DLength\_Spheroid alias

This function supports 3d and will not drop the z-index.

### Examples

```
SELECT ST_LengthSpheroid(geometry_column,
 'SPHEROID["GRS_1980",6378137,298.257222101]')
 FROM geometry_table;

SELECT ST_LengthSpheroid(the_geom, sph_m) As tot_len,
ST_LengthSpheroid(ST_GeometryN(the_geom,1), sph_m) As len_line1,
ST_LengthSpheroid(ST_GeometryN(the_geom,2), sph_m) As len_line2
 FROM (SELECT ST_GeomFromText('MULTILINESTRING((-118.584 38.374,-118.583 38.5),
 (-71.05957 42.3589 , -71.061 43))') As the_geom,
 CAST('SPHEROID["GRS_1980",6378137,298.257222101]' As spheroid) As sph_m) as foo;
 tot_len | len_line1 | len_line2
-----+-----+-----
85204.5207562955 | 13986.8725229309 | 71217.6482333646

--3D
SELECT ST_LengthSpheroid(the_geom, sph_m) As tot_len,
ST_LengthSpheroid(ST_GeometryN(the_geom,1), sph_m) As len_line1,
ST_LengthSpheroid(ST_GeometryN(the_geom,2), sph_m) As len_line2
 FROM (SELECT ST_GeomFromEWKT('MULTILINESTRING((-118.584 38.374 20,-118.583 38.5 30) ←
 (-71.05957 42.3589 75, -71.061 43 90))') As the_geom,
 CAST('SPHEROID["GRS_1980",6378137,298.257222101]' As spheroid) As sph_m) as foo;
 tot_len | len_line1 | len_line2
-----+-----+-----
85204.5259107402 | 13986.876097711 | 71217.6498130292
```

**See Also**[ST\\_GeometryN](#), [ST\\_Length](#)**8.9.41 ST\_Length2D\_Spheroid**

`ST_Length2D_Spheroid` — Calculates the 2D length/perimeter of a geometry on an ellipsoid. This is useful if the coordinates of the geometry are in longitude/latitude and a length is desired without reprojection.

**Synopsis**

```
float ST_Length2D_Spheroid(geometry a_geometry, spheroid a_spheroid);
```

**Description**

Calculates the 2D length/perimeter of a geometry on an ellipsoid. This is useful if the coordinates of the geometry are in longitude/latitude and a length is desired without reprojection. The ellipsoid is a separate database type and can be constructed as follows:

```
SPHEROID [<NAME>, <SEMI-MAJOR AXIS>, <INVERSE FLATTENING>]
```

```
SPHEROID ["GRS_1980", 6378137, 298.257222101]
```

**Note**

This is much like [ST\\_LengthSpheroid](#) except it will ignore the Z ordinate in calculations.

**Examples**

```
SELECT ST_Length2D_Spheroid(geometry_column,
 'SPHEROID["GRS_1980", 6378137, 298.257222101]')
 FROM geometry_table;

SELECT ST_Length2D_Spheroid(the_geom, sph_m) As tot_len,
ST_Length2D_Spheroid(ST_GeometryN(the_geom,1), sph_m) As len_line1,
ST_Length2D_Spheroid(ST_GeometryN(the_geom,2), sph_m) As len_line2
 FROM (SELECT ST_GeomFromText('MULTILINESTRING((-118.584 38.374,-118.583 38.5),
 (-71.05957 42.3589 , -71.061 43))') As the_geom,
CAST('SPHEROID["GRS_1980", 6378137, 298.257222101]' As spheroid) As sph_m) as foo;

## 8.9.42 ST\_LongestLine

`ST_LongestLine` — Returns the 2-dimensional longest line points of two geometries. The function will only return the first longest line if more than one, that the function finds. The line returned will always start in `g1` and end in `g2`. The length of the line this function returns will always be the same as `st_maxdistance` returns for `g1` and `g2`.

### Synopsis

```
geometry ST_LongestLine(geometry g1, geometry g2);
```

### Description

Returns the 2-dimensional longest line between the points of two geometries.

Availability: 1.5.0

### Examples

---

*Longest line between point and line*

```

SELECT ST_AsText (
 ST_LongestLine('POINT(100 100) ':: geometry,
 'LINESTRING (20 80, 98 190, 110 180, 50 75) '::geometry)
) As lline;

lline

LINESTRING(100 100,98 190)

```

*longest line between polygon and polygon*

```

SELECT ST_AsText (
 ST_LongestLine(
 ST_GeomFromText ('POLYGON ((175 150, 20 40, 50 60, 125 100, 175 150))'),
 ST_Buffer(ST_GeomFromText ('POINT(110 170)'), 20)
) As llinewkt;

lline

LINESTRING(20 40,121.111404660392 186.629392246051)

```

*longest straight distance to travel from one part of an elegant city to the other Note the max distance = to the length of the line.*

```
SELECT ST_AsText(ST_LongestLine(c.the_geom, c.the_geom)) As llinewkt,
 ST_MaxDistance(c.the_geom,c.the_geom) As max_dist,
 ST_Length(ST_LongestLine(c.the_geom, c.the_geom)) As lenll
FROM (SELECT ST_BuildArea(ST_Collect(the_geom)) As the_geom
 FROM (SELECT ST_Translate(ST_SnapToGrid(ST_Buffer(ST_Point(50 ,generate_series ↵
(50,190, 50)
),40, 'quad_segs=2'),1), x, 0) As the_geom
 FROM generate_series(1,100,50) As x) AS foo
) As c;
```

llinewkt	max_dist	lenll
LINESTRING(23 22,129 178)	188.605408193933	188.605408193933

### 8.9.43 ST\_OrderingEquals

`ST_OrderingEquals` — Returns true if the given geometries represent the same geometry and points are in the same directional order.

#### Synopsis

boolean `ST_OrderingEquals`(geometry A, geometry B);

#### Description

`ST_OrderingEquals` compares two geometries and returns t (TRUE) if the geometries are equal and the coordinates are in the same order; otherwise it returns f (FALSE).

**Note**

This function is implemented as per the ArcSDE SQL specification rather than SQL-MM. [http://edndoc.esri.com/arcsde/9.1/sql\\_api/sqlapi3.htm#ST\\_OrderingEquals](http://edndoc.esri.com/arcsde/9.1/sql_api/sqlapi3.htm#ST_OrderingEquals)

This method implements the SQL/MM specification. SQL-MM 3: 5.1.43

**Examples**

```
SELECT ST_OrderingEquals(ST_GeomFromText('LINESTRING(0 0, 10 10)'),
 ST_GeomFromText('LINESTRING(0 0, 5 5, 10 10)'));
 st_orderingequals

f
(1 row)

SELECT ST_OrderingEquals(ST_GeomFromText('LINESTRING(0 0, 10 10)'),
 ST_GeomFromText('LINESTRING(0 0, 0 0, 10 10)'));
 st_orderingequals

t
(1 row)

SELECT ST_OrderingEquals(ST_Reverse(ST_GeomFromText('LINESTRING(0 0, 10 10)'),
 ST_GeomFromText('LINESTRING(0 0, 0 0, 10 10)'));
 st_orderingequals

f
(1 row)
```

**See Also**

[ST\\_Equals](#), [ST\\_Reverse](#)

**8.9.44 ST\_Overlaps**

**ST\_Overlaps** — Returns TRUE if the Geometries share space, are of the same dimension, but are not completely contained by each other.

**Synopsis**

boolean **ST\_Overlaps**(geometry A, geometry B);

**Description**

Returns TRUE if the Geometries "spatially overlap". By that we mean they intersect, but one does not completely contain another. Performed by the GEOS module

**Note**

Do not call with a GeometryCollection as an argument

This function call will automatically include a bounding box comparison that will make use of any indexes that are available on the geometries. To avoid index use, use the function `_ST_Overlaps`.

NOTE: this is the "allowable" version that returns a boolean, not an integer.

- ✓ This method implements the [OpenGIS Simple Features Implementation Specification for SQL 1.1. s2.1.1.2 // s2.1.13.3](#)
- ✓ This method implements the SQL/MM specification. SQL-MM 3: 5.1.32

### Examples

The following illustrations all return TRUE.

```
--a point on a line is contained by the line and is of a lower dimension, and therefore ↩
does not overlap the line
nor crosses

SELECT ST_Overlaps(a,b) As a_overlap_b,
 ST_Crosses(a,b) As a_crosses_b,
 ST_Intersects(a, b) As a_intersects_b, ST_Contains(b,a) As b_contains_a
FROM (SELECT ST_GeomFromText('POINT(1 0.5)') As a, ST_GeomFromText('LINESTRING(1 0, 1 1, 3 ↩
5)') As b)
As foo

a_overlap_b | a_crosses_b | a_intersects_b | b_contains_a
-----+-----+-----+-----
f | f | t | t

--a line that is partly contained by circle, but not fully is defined as intersecting and ↩
crossing,
-- but since of different dimension it does not overlap
SELECT ST_Overlaps(a,b) As a_overlap_b, ST_Crosses(a,b) As a_crosses_b,

8.9.45 ST\_Perimeter

ST\_Perimeter — Return the length measurement of the boundary of an ST\_Surface or ST\_MultiSurface geometry or geography. (Polygon, MultiPolygon). geometry measurement is in units of spatial reference and geography is in meters.

Synopsis

```
float ST_Perimeter(geometry g1);
float ST_Perimeter(geography geog, boolean use_spheroid=true);
```

Description

Returns the 2D perimeter of the geometry/geography if it is a ST\_Surface, ST\_MultiSurface (Polygon, MultiPolygon). 0 is returned for non-areal geometries. For linear geometries use ST\_Length. For geometry types, units for perimeter measures are specified by the spatial reference system of the geometry.

For geography types, the calculations are performed using the inverse geodesic problem, where perimeter units are in meters. If PostGIS is compiled with PROJ version 4.8.0 or later, the spheroid is specified by the SRID, otherwise it is exclusive to WGS84. If use\_spheroid=false, then calculations will approximate a sphere instead of a spheroid.

Currently this is an alias for ST\_Perimeter2D, but this may change to support higher dimensions.

This method implements the [OpenGIS Simple Features Implementation Specification for SQL 1.1](#). s2.1.5.1

This method implements the SQL/MM specification. SQL-MM 3: 8.1.3, 9.5.4

Availability 2.0.0: Support for geography was introduced

**Examples: Geometry**

Return perimeter in feet for Polygon and MultiPolygon. Note this is in feet because EPSG:2249 is Massachusetts State Plane Feet

```

### 8.9.46 ST\_Perimeter2D

`ST_Perimeter2D` — Returns the 2-dimensional perimeter of the geometry, if it is a polygon or multi-polygon. This is currently an alias for `ST_Perimeter`.

#### Synopsis

```
float ST_Perimeter2D(geometry geomA);
```

#### Description

Returns the 2-dimensional perimeter of the geometry, if it is a polygon or multi-polygon.

#### Note

This is currently an alias for `ST_Perimeter`. In future versions `ST_Perimeter` may return the highest dimension perimeter for a geometry. This is still under consideration

## See Also

[ST\\_Perimeter](#)

### 8.9.47 ST\_3DPerimeter

`ST_3DPerimeter` — Returns the 3-dimensional perimeter of the geometry, if it is a polygon or multi-polygon.

#### Synopsis

```
float ST_3DPerimeter(geometry geomA);
```

#### Description

Returns the 3-dimensional perimeter of the geometry, if it is a polygon or multi-polygon. If the geometry is 2-dimensional, then the 2-dimensional perimeter is returned.

This function supports 3d and will not drop the z-index.

Changed: 2.0.0 In prior versions this used to be called `ST_Perimeter3D`

## Examples

Perimeter of a slightly elevated polygon in the air in Massachusetts state plane feet

```
SELECT ST_3DPerimeter(the_geom), ST_Perimeter2d(the_geom), ST_Perimeter(the_geom) FROM
 (SELECT ST_GeomFromEWKT('SRID=2249;POLYGON((743238 2967416 2,743238 2967450 1,
743265.625 2967416 1,743238 2967416 2))') As the_geom) As foo;
```

ST_3DPerimeter	st_perimeter2d	st_perimeter
105.465793597674	105.432997272188	105.432997272188

## See Also

## 8.9.48 ST\_PointOnSurface

`ST_PointOnSurface` — Returns a `POINT` guaranteed to lie on the surface.

### Synopsis

geometry `ST_PointOnSurface`(geometry g1);

### Description

Returns a `POINT` guaranteed to intersect a surface.

This method implements the [OpenGIS Simple Features Implementation Specification for SQL 1.1](#). s3.2.14.2 // s3.2.18.2

This method implements the SQL/MM specification. SQL-MM 3: 8.1.5, 9.5.6. According to the specs, `ST_PointOnSurface` works for surface geometries (POLYGONS, MULTIPOLYGONS, CURVED POLYGONS). So PostGIS seems to be extending what the spec allows here. Most databases Oracle, DB II, ESRI SDE seem to only support this function for surfaces. SQL Server 2008 like PostGIS supports for all common geometries.

This function supports 3d and will not drop the z-index.

### Examples

```
SELECT ST_AsText(ST_PointOnSurface('POINT(0 5)::geometry'));
 st_astext
```

```

POINT(0 5)
(1 row)
```

```
SELECT ST_AsText(ST_PointOnSurface('LINESTRING(0 5, 0 10)::geometry'));
 st_astext
```

```

POINT(0 5)
(1 row)
```

```
SELECT ST_AsText(ST_PointOnSurface('POLYGON((0 0, 0 5, 5 5, 5 0, 0 0))::geometry));
```

```

 st_astext

POINT(2.5 2.5)
(1 row)

SELECT ST_AsEWKT(ST_PointOnSurface(ST_GeomFromEWKT('LINESTRING(0 5 1, 0 0 1, 0 10 2)')));
 st_asewkt

POINT(0 0 1)
(1 row)

```

**See Also**

[ST\\_Centroid](#), [ST\\_PointInsideCircle](#)

**8.9.49 ST\_Project**

**ST\_Project** — Returns a `POINT` projected from a start point using a distance in meters and bearing (azimuth) in radians.

**Synopsis**

```
geography ST_Project(geography g1, float distance, float azimuth);
```

**Description**

Returns a `POINT` projected along a geodesic from a start point using an azimuth (bearing) measured in radians and distance measured in meters. This is also called a direct geodesic problem.

The azimuth is sometimes called the heading or the bearing in navigation. It is measured relative to true north (azimuth zero). East is azimuth 90 ( $\pi/2$ ), south is azimuth 180 ( $\pi$ ), west is azimuth 270 ( $3\pi/2$ ).

The distance is given in meters.

Availability: 2.0.0

**Example: Using degrees - projected point 100,000 meters and bearing 45 degrees**

```

SELECT ST_AsText(ST_Project('POINT(0 0)::geography, 100000, radians(45.0)));

 st_astext

POINT(0.635231029125537 0.639472334729198)
(1 row)

```

**See Also**

[ST\\_Azimuth](#), [ST\\_Distance](#), [PostgreSQL Math Functions](#)

**8.9.50 ST\_Relate**

**ST\_Relate** — Returns true if this Geometry is spatially related to anotherGeometry, by testing for intersections between the Interior, Boundary and Exterior of the two geometries as specified by the values in the `intersectionMatrixPattern`. If no `intersectionMatrixPattern` is passed in, then returns the maximum `intersectionMatrixPattern` that relates the 2 geometries.

## Synopsis

```
boolean ST_Relate(geometry geomA, geometry geomB, text intersectionMatrixPattern);
text ST_Relate(geometry geomA, geometry geomB);
text ST_Relate(geometry geomA, geometry geomB, integer BoundaryNodeRule);
```

## Description

Version 1: Takes geomA, geomB, intersectionMatrix and Returns 1 (TRUE) if this Geometry is spatially related to another Geometry, by testing for intersections between the Interior, Boundary and Exterior of the two geometries as specified by the values in the [DE-9IM matrix pattern](#).

This is especially useful for testing compound checks of intersection, crosses, etc in one step.

Do not call with a GeometryCollection as an argument

### Note

This is the "allowable" version that returns a boolean, not an integer. This is defined in OGC spec

### Note

This DOES NOT automatically include an index call. The reason for that is some relationships are anti e.g. Disjoint. If you are using a relationship pattern that requires intersection, then include the && index call.

Version 2: Takes geomA and geomB and returns the [Section 4.3.6](#)

Version 3: same as version 2, but allows to specify a boundary node rule (1:OGC/MOD2, 2:Endpoint, 3:MultivalentEndpoint, 4:MonovalentEndpoint)

### Note

Do not call with a GeometryCollection as an argument

not in OGC spec, but implied. see [s2.1.13.2](#)

Performed by the GEOS module

This method implements the [OpenGIS Simple Features Implementation Specification for SQL 1.1](#). [s2.1.1.2](#) // [s2.1.13.3](#)

This method implements the SQL/MM specification. SQL-MM 3: 5.1.25

Enhanced: 2.0.0 - added support for specifying boundary node rule (requires GEOS >= 3.0).

## Examples

```
--Find all compounds that intersect and not touch a poly (interior intersects)
SELECT l.* , b.name As poly_name
 FROM polys As b
 INNER JOIN compounds As l
 ON (p.the_geom && b.the_geom
 AND ST_Relate(l.the_geom, b.the_geom, 'T*****'));
```

```

SELECT ST_Relate(ST_GeometryFromText('POINT(1 2)'), ST_Buffer(ST_GeometryFromText('POINT(1 2)'),2));
st_relate

0FFFFFF212

SELECT ST_Relate(ST_GeometryFromText('LINESTRING(1 2, 3 4)'), ST_GeometryFromText('LINESTRING(5 6, 7 8)'));
st_relate

FF1FF0102

SELECT ST_Relate(ST_GeometryFromText('POINT(1 2)'), ST_Buffer(ST_GeometryFromText('POINT(1 2)'),2), '0FFFFFF212');
st_relate

t

SELECT ST_Relate(ST_GeometryFromText('POINT(1 2)'), ST_Buffer(ST_GeometryFromText('POINT(1 2)'),2), '*FF*FF212');
st_relate

t

```

**See Also**

[ST\\_Crosses](#), [Section 4.3.6](#), [ST\\_Disjoint](#), [ST\\_Intersects](#), [ST\\_Touches](#)

**8.9.51 ST\_RelateMatch**

`ST_RelateMatch` — Returns true if `intersectionMatrixPattern1` implies `intersectionMatrixPattern2`

**Synopsis**

boolean `ST_RelateMatch`(text `intersectionMatrix`, text `intersectionMatrixPattern`);

**Description**

Takes `intersectionMatrix` and `intersectionMatrixPattern` and Returns true if the `intersectionMatrix` satisfies the `intersectionMatrixPattern`. For more information refer to [Section 4.3.6](#).

Availability: 2.0.0 - requires GEOS >= 3.3.0.

**Examples**

```

SELECT ST_RelateMatch('101202FFF', 'TTTTTFFF') ;
-- result --
t
--example of common intersection matrix patterns and example matrices
-- comparing relationships of involving one invalid geometry and (a line and polygon that intersect at interior and boundary)
SELECT mat.name, pat.name, ST_RelateMatch(mat.val, pat.val) As satisfied
FROM
 (VALUES ('Equality', 'T1FF1FFF1'),
 ('Overlaps', 'T*T***T**'),

```

```
 ('Within', 'T**F**F***'),
 ('Disjoint', 'FF**FF***') As pat(name,val)
CROSS JOIN
 (VALUES ('Self intersections (invalid)', '111111111'),
 ('IE2_BI1_BB0_BE1_EI1_EE2', 'FF2101102'),
 ('IB1_IE1_BB0_BE0_EI2_EI1_EE2', 'F11F00212')
) As mat(name,val);
```

## 8.9.52 ST\_ShortestLine

`ST_ShortestLine` — Returns the 2-dimensional shortest line between two geometries

### Synopsis

```
geometry ST_ShortestLine(geometry g1, geometry g2);
```

### Description

Returns the 2-dimensional shortest line between two geometries. The function will only return the first shortest line if more than one, that the function finds. If g1 and g2 intersects in just one point the function will return a line with both start and end in that intersection-point. If g1 and g2 are intersecting with more than one point the function will return a line with start and end in the same point but it can be any of the intersecting points. The line returned will always start in g1 and end in g2. The length of the line this function returns will always be the same as `ST_Distance` returns for g1 and g2.

Availability: 1.5.0

### Examples

---

 <p><i>Shortest line between point and linestring</i></p> <pre>SELECT ST_AsText(   ST_ShortestLine('POINT(100 100) ←     '::geometry,     'LINESTRING (20 80, 98 ←       190, 110 180, 50 75 )'::geometry)   ) As sline;  sline ----- LINESTRING(100 100,73.0769230769231 ←   115.384615384615)</pre>	 <p><i>shortest line between polygon and polygon</i></p> <pre>SELECT ST_AsText(   ST_ShortestLine(     ST_GeomFromText(' ←       POLYGON((175 150, 20 40, 50 60, 125         ST_Buffer( ←           ST_GeomFromText('POINT(110 170)'), 2         )       ) As slinewkt;  LINESTRING(140.752120669087 ←   125.695053378061,121.111404660392 15</pre>
----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------	---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------

**See Also**

[ST\\_ClosestPoint](#), [ST\\_Distance](#), [ST\\_LongestLine](#), [ST\\_MaxDistance](#)

**8.9.53 ST\_Touches**

**ST\_Touches** — Returns TRUE if the geometries have at least one point in common, but their interiors do not intersect.

**Synopsis**

boolean **ST\_Touches**(geometry g1, geometry g2);

**Description**

Returns TRUE if the only points in common between *g1* and *g2* lie in the union of the boundaries of *g1* and *g2*. The `ST_Touches` relation applies to all Area/Area, Line/Line, Line/Area, Point/Area and Point/Line pairs of relationships, but *not* to the Point/Point pair.

In mathematical terms, this predicate is expressed as:

$$a.Touches(b) \Leftrightarrow (I(a) \cap I(b) = \emptyset) \wedge (a \cap b) \neq \emptyset$$

The allowable DE-9IM Intersection Matrices for the two geometries are:

- FT\*\*\*\*\*
- F\*\*T\*\*\*\*\*
- F\*\*\*T\*\*\*\*\*

### Important

Do not call with a `GEOMETRYCOLLECTION` as an argument

### Note

This function call will automatically include a bounding box comparison that will make use of any indexes that are available on the geometries. To avoid using an index, use `_ST_Touches` instead.

This method implements the [OpenGIS Simple Features Implementation Specification for SQL 1.1](#). s2.1.1.2 // s2.1.13.3

This method implements the SQL/MM specification. SQL-MM 3: 5.1.28

### Examples

The `ST_Touches` predicate returns `TRUE` in all the following illustrations.

```
SELECT ST_Touches('LINestring(0 0, 1 1, 0 2)::geometry, 'POINT(1 1)::geometry');
st_touches

f
(1 row)

SELECT ST_Touches('LINestring(0 0, 1 1, 0 2)::geometry, 'POINT(0 2)::geometry');
st_touches

t
(1 row)
```

### 8.9.54 ST\_Within

**ST\_Within** — Returns true if the geometry A is completely inside geometry B

#### Synopsis

boolean **ST\_Within**(geometry A, geometry B);

#### Description

Returns TRUE if geometry A is completely inside geometry B. For this function to make sense, the source geometries must both be of the same coordinate projection, having the same SRID. It is a given that if **ST\_Within**(A,B) is true and **ST\_Within**(B,A) is true, then the two geometries are considered spatially equal.

Performed by the GEOS module

Enhanced: 2.3.0 Enhancement to PIP short-circuit for geometry extended to support MultiPoints with few points. Prior versions only supported point in polygon.

#### Important

Do not call with a `GEOMETRYCOLLECTION` as an argument

**Important**

Do not use this function with invalid geometries. You will get unexpected results.

This function call will automatically include a bounding box comparison that will make use of any indexes that are available on the geometries. To avoid index use, use the function `_ST_Within`.

NOTE: this is the "allowable" version that returns a boolean, not an integer.

This method implements the [OpenGIS Simple Features Implementation Specification for SQL 1.1](#). s2.1.1.2 // s2.1.13.3 - a.Relate(b, 'T\*\*F\*\*F\*\*\*')

This method implements the SQL/MM specification. SQL-MM 3: 5.1.30

**Examples**

```
--a circle within a circle
SELECT ST_Within(smallc,smallc) As smallinsmall,
 ST_Within(smallc, bigc) As smallinbig,
 ST_Within(bigc,smallc) As biginsmall,
 ST_Within(ST_Union(smallc, bigc), bigc) as unioninbig,
 ST_Within(bigc, ST_Union(smallc, bigc)) as biginunion,
 ST_Equals(bigc, ST_Union(smallc, bigc)) as bigisunion
FROM
(
SELECT ST_Buffer(ST_GeomFromText('POINT(50 50)'), 20) As smallc,
 ST_Buffer(ST_GeomFromText('POINT(50 50)'), 40) As bigc) As foo;
--Result
smallinsmall | smallinbig | biginsmall | unioninbig | biginunion | bigisunion
-----+-----+-----+-----+-----+-----
t | t | f | t | t | t
(1 row)
```

## 8.10 SFCGAL Functions

### 8.10.1 `postgis_sfcgal_version`

`postgis_sfcgal_version` — Returns the version of SFCGAL in use

#### Synopsis

```
text postgis_sfcgal_version(void);
```

#### Description

Availability: 2.1.0

This method needs SFCGAL backend.

This function supports 3d and will not drop the z-index.

This function supports Polyhedral surfaces.

This function supports Triangles and Triangulated Irregular Network Surfaces (TIN).

### 8.10.2 `ST_Extrude`

`ST_Extrude` — Extrude a surface to a related volume

#### Synopsis

```
geometry ST_Extrude(geometry geom, float x, float y, float z);
```

#### Description

Availability: 2.1.0

This method needs SFCGAL backend.

This function supports 3d and will not drop the z-index.

This function supports Polyhedral surfaces.

This function supports Triangles and Triangulated Irregular Network Surfaces (TIN).

## Examples

3D images were generated using PostGIS [ST\\_AsX3D](#) and rendering in HTML using [X3Dom HTML Javascript rendering library](#).

<pre>SELECT ST_Buffer(ST_GeomFromText('POINT ↵ (100 90)'), 50, 'quad_segs=2'),0,0,30);</pre>  <p><i>Original octagon formed from buffering point</i></p>	<pre>ST_Extrude(ST_Buffer(ST_GeomFromText(' ↵ POINT(100 90)'), 50, 'quad_segs=2'),0,0,30);</pre>  <p><i>Hexagon extruded 30 units along Z produces a PolyhedralSurfaceZ</i></p>
<pre>SELECT ST_GeomFromText('LINESTRING(50 50, ↵ 100 90, 95 150)')</pre>  <p><i>Original linestring</i></p>	<pre>SELECT ST_Extrude( ST_GeomFromText('LINESTRING(50 50, 100 ↵ 90, 95 150)'),0,0,10);</pre>  <p><i>LineString Extruded along Z produces a PolyhedralSurfaceZ</i></p>

**See Also**[ST\\_AsX3D](#)**8.10.3 ST\_StraightSkeleton**

ST\_StraightSkeleton — Compute a straight skeleton from a geometry

**Synopsis**

geometry **ST\_StraightSkeleton**(geometry geom);

**Description**

Availability: 2.1.0

This method needs SFCGAL backend.

This function supports 3d and will not drop the z-index.

This function supports Polyhedral surfaces.

This function supports Triangles and Triangulated Irregular Network Surfaces (TIN).

**Examples**

```
SELECT ST_StraightSkeleton(ST_GeomFromText('POLYGON ((190 190, 10 190, 10 10, 190 10, 190 ←
20, 160 30, 60 30, 60 130, 190 140, 190 190))'));
```

## 8.10.4 ST\_ApproximateMedialAxis

ST\_ApproximateMedialAxis — Compute the approximate medial axis of an areal geometry.

### Synopsis

geometry **ST\_ApproximateMedialAxis**(geometry geom);

### Description

Return an approximate medial axis for the areal input based on its straight skeleton. Uses an SFCGAL specific API when built against a capable version (1.2.0+). Otherwise the function is just a wrapper around ST\_StraightSkeleton (slower case).

Availability: 2.2.0

This method needs SFCGAL backend.

This function supports 3d and will not drop the z-index.

This function supports Polyhedral surfaces.

This function supports Triangles and Triangulated Irregular Network Surfaces (TIN).

### Examples

```
SELECT ST_ApproximateMedialAxis(ST_GeomFromText('POLYGON ((190 190, 10 190, 10 10, 190 10, ←
190 20, 160 30, 60 30, 60 130, 190 140, 190 190))'));
```

*A polygon and its approximate medial axis*

**See Also**

[ST\\_StraightSkeleton](#)

### 8.10.5 ST\_IsPlanar

ST\_IsPlanar — Check if a surface is or not planar

**Synopsis**

boolean **ST\_IsPlanar**(geometry geom);

**Description**

Availability: 2.2.0: This was documented in 2.1.0 but got accidentally left out in 2.1 release.

This method needs SFCGAL backend.

This function supports 3d and will not drop the z-index.

This function supports Polyhedral surfaces.

This function supports Triangles and Triangulated Irregular Network Surfaces (TIN).

### 8.10.6 ST\_Orientation

ST\_Orientation — Determine surface orientation

**Synopsis**

integer **ST\_Orientation**(geometry geom);

**Description**

The function only applies to polygons. It returns -1 if the polygon is counterclockwise oriented and 1 if the polygon is clockwise oriented.

Availability: 2.1.0

This method needs SFCGAL backend.

This function supports 3d and will not drop the z-index.

### 8.10.7 ST\_ForceLHR

ST\_ForceLHR — Force LHR orientation

**Synopsis**

geometry **ST\_ForceLHR**(geometry geom);

---

## Description

Availability: 2.1.0

This method needs SFCGAL backend.

This function supports 3d and will not drop the z-index.

This function supports Polyhedral surfaces.

This function supports Triangles and Triangulated Irregular Network Surfaces (TIN).

## 8.10.8 ST\_MinkowskiSum

ST\_MinkowskiSum — Performs Minkowski sum

### Synopsis

```
geometry ST_MinkowskiSum(geometry geom1, geometry geom2);
```

### Description

This function performs a 2D minkowski sum of a point, line or polygon with a polygon.

A minkowski sum of two geometries A and B is the set of all points that are the sum of any point in A and B. Minkowski sums are often used in motion planning and computer-aided design. More details on [Wikipedia Minkowski addition](#).

The first parameter can be any 2D geometry (point, linestring, polygon). If a 3D geometry is passed, it will be converted to 2D by forcing Z to 0, leading to possible cases of invalidity. The second parameter must be a 2D polygon.

Implementation utilizes [CGAL 2D Minkowskisum](#).

Availability: 2.1.0

This method needs SFCGAL backend.

### Examples

Minkowski Sum of Linestring and circle polygon where Linestring cuts thru the circle

---

```

SELECT ST_MinkowskiSum(line, circle)
FROM (SELECT
 ST_MakeLine(ST_MakePoint(10, 10),ST_MakePoint(100, 100)) As line,
 ST_Buffer(ST_GeomFromText('POINT(50 50)'), 30) As circle) As foo;

)
```

### 8.10.9 ST\_3DIntersection

ST\_3DIntersection — Perform 3D intersection

#### Synopsis

geometry **ST\_3DIntersection**(geometry geom1, geometry geom2);

#### Description

Return a geometry that is the shared portion between geom1 and geom2.

Availability: 2.1.0

This method needs SFCGAL backend.

This function supports 3d and will not drop the z-index.

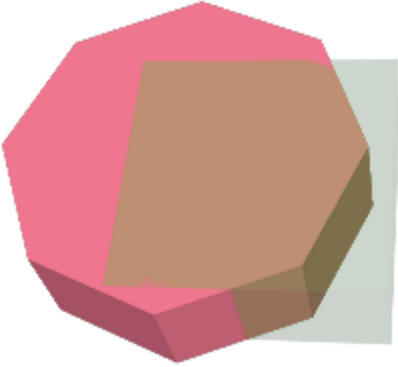

This function supports Polyhedral surfaces.

This function supports Triangles and Triangulated Irregular Network Surfaces (TIN).

## Examples

3D images were generated using PostGIS [ST\\_AsX3D](#) and rendering in HTML using [X3Dom HTML Javascript rendering library](#).

<pre>SELECT ST_Extrude(ST_Buffer( ←   ST_GeomFromText('POINT(100 90)'),   50, 'quad_segs=2'),0,0,30) AS geom1,   ST_Extrude(ST_Buffer( ←   ST_GeomFromText('POINT(80 80)'),   50, 'quad_segs=1'),0,0,30) AS geom2;</pre>  <p><i>Original 3D geometries overlaid. geom2 is shown semi-transparent</i></p>	<pre>SELECT ST_3DIntersection(geom1,geom2) FROM ( SELECT ST_Extrude(ST_Buffer( ←   ST_GeomFromText('POINT(100 90)'),   50, 'quad_segs=2'),0,0,30) AS geom1,   ST_Extrude(ST_Buffer( ←   ST_GeomFromText('POINT(80 80)'),   50, 'quad_segs=1'),0,0,30) AS geom2 ) As ←   t;</pre>  <p><i>Intersection of geom1 and geom2</i></p>
--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------	--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------

## 3D linestrings and polygons

```
SELECT ST_AsText(ST_3DIntersection(linestring, polygon)) As wkt
FROM ST_GeomFromText('LINESTRING Z (2 2 6,1.5 1.5 7,1 1 8,0.5 0.5 8,0 0 10)') AS ←
 linestring
CROSS JOIN ST_GeomFromText('POLYGON((0 0 8, 0 1 8, 1 1 8, 1 0 8, 0 0 8))') AS polygon;
```

wkt

-----

```
LINESTRING Z (1 1 8,0.5 0.5 8)
```

## Cube (closed Polyhedral Surface) and Polygon Z

```
SELECT ST_AsText(ST_3DIntersection(
 ST_GeomFromText('POLYHEDRALSURFACE Z(((0 0 0, 0 0 1, 0 1 1, 0 1 0, 0 0 0)),
 ((0 0 0, 0 1 0, 1 1 0, 1 0 0, 0 0 0)), ((0 0 0, 1 0 0, 1 0 1, 0 0 1, 0 0 0)),
 ((1 1 0, 1 1 1, 1 0 1, 1 0 0, 1 1 0)),
 ((0 1 0, 0 1 1, 1 1 1, 1 1 0, 0 1 0)), ((0 0 1, 1 0 1, 1 1 1, 0 1 1, 0 0 1)))'),
 'POLYGON Z ((0 0 0, 0 0 0.5, 0 0.5 0.5, 0 0.5 0, 0 0 0))'::geometry))
```

```
TIN Z (((0 0 0,0 0 0.5,0 0.5 0.5,0 0 0)),((0 0.5 0,0 0 0,0 0.5 0.5,0 0.5 0)))
```

Intersection of 2 solids that result in volumetric intersection is also a solid (ST\_Dimension returns 3)

```

SELECT ST_AsText(ST_3DIntersection(ST_Extrude(ST_Buffer('POINT(10 20)::geometry,10,1) ←
,0,0,30),
ST_Extrude(ST_Buffer('POINT(10 20)::geometry,10,1),2,0,10)));

```

### 8.10.10 ST\_3DDifference

ST\_3DDifference — Perform 3D difference

#### Synopsis

geometry **ST\_3DDifference**(geometry geom1, geometry geom2);

#### Description

Returns that part of geom1 that is not part of geom2.

Availability: 2.2.0

This method needs SFCGAL backend.

This function supports 3d and will not drop the z-index.

This function supports Polyhedral surfaces.

This function supports Triangles and Triangulated Irregular Network Surfaces (TIN).

#### Examples

3D images were generated using PostGIS [ST\\_AsX3D](#) and rendering in HTML using [X3Dom HTML Javascript rendering library](#).

```
SELECT ST_Extrude(ST_Buffer(↵
 ST_GeomFromText('POINT(100 90)'),
 50, 'quad_segs=2'),0,0,30) AS geom1,
 ST_Extrude(ST_Buffer(↵
 ST_GeomFromText('POINT(80 80)'),
 50, 'quad_segs=1'),0,0,30) AS geom2;
```

*Original 3D geometries overlaid. geom2 is the part that will be removed.*

```
SELECT ST_3DDifference(geom1,geom2)
FROM (SELECT ST_Extrude(ST_Buffer(↵
 ST_GeomFromText('POINT(100 90)'),
 50, 'quad_segs=2'),0,0,30) AS geom1,
 ST_Extrude(ST_Buffer(↵
 ST_GeomFromText('POINT(80 80)'),
 50, 'quad_segs=1'),0,0,30) AS geom2) As ↵
t;
```

*What's left after removing geom2*

### 8.10.11 ST\_3DUnion

ST\_3DUnion — Perform 3D union

#### Synopsis

geometry **ST\_3DUnion**(geometry geom1, geometry geom2);

#### Description

Availability: 2.2.0

This method needs SFCGAL backend.

This function supports 3d and will not drop the z-index.

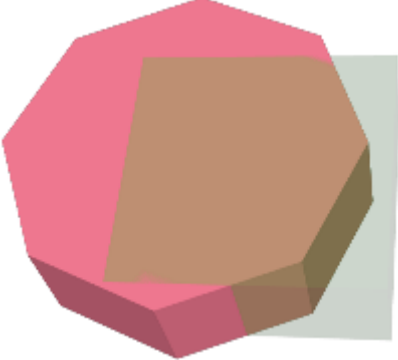

This function supports Polyhedral surfaces.

This function supports Triangles and Triangulated Irregular Network Surfaces (TIN).

## Examples

3D images were generated using PostGIS [ST\\_AsX3D](#) and rendering in HTML using [X3Dom HTML Javascript rendering library](#).

<pre>SELECT ST_Extrude(ST_Buffer( ↵   ST_GeomFromText('POINT(100 90)'),   50, 'quad_segs=2'),0,0,30) AS geom1,   ST_Extrude(ST_Buffer( ↵   ST_GeomFromText('POINT(80 80)'),   50, 'quad_segs=1'),0,0,30) AS geom2;</pre>  <p><i>Original 3D geometries overlaid. geom2 is the one with transparency.</i></p>	<pre>SELECT ST_3DUnion(geom1,geom2) FROM ( SELECT ST_Extrude(ST_Buffer( ↵   ST_GeomFromText('POINT(100 90)'),   50, 'quad_segs=2'),0,0,30) AS geom1,   ST_Extrude(ST_Buffer( ↵   ST_GeomFromText('POINT(80 80)'),   50, 'quad_segs=1'),0,0,30) AS geom2 ) As ↵   t;</pre>  <p><i>Union of geom1 and geom2</i></p>
------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------	------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------

### 8.10.12 ST\_3DArea

**ST\_3DArea** — Computes area of 3D surface geometries. Will return 0 for solids.

#### Synopsis

```
floatST_3DArea(geometry geom1);
```

#### Description

Availability: 2.1.0

This method needs SFCGAL backend.

This function supports 3d and will not drop the z-index.

This function supports Polyhedral surfaces.

This function supports Triangles and Triangulated Irregular Network Surfaces (TIN).

## Examples

Note: By default a PolyhedralSurface built from WKT is a surface geometry, not solid. It therefore has surface area. Once converted to a solid, no area.

```
SELECT ST_3DArea(geom) As cube_surface_area,
 ST_3DArea(ST_MakeSolid(geom)) As solid_surface_area
FROM (SELECT 'POLYHEDRALSURFACE(((0 0 0, 0 0 1, 0 1 1, 0 1 0, 0 0 0)),
 ((0 0 0, 0 1 0, 1 1 0, 1 0 0, 0 0 0)),
 ((0 0 0, 1 0 0, 1 0 1, 0 0 1, 0 0 0)),
 ((1 1 0, 1 1 1, 1 0 1, 1 0 0, 1 1 0)),
 ((0 1 0, 0 1 1, 1 1 1, 1 1 0, 0 1 0)),
 ((0 0 1, 1 0 1, 1 1 1, 0 1 1, 0 0 1)))'::geometry) As f(geom);
```

cube_surface_area	solid_surface_area
6	0

### 8.10.13 ST\_Tessellate

ST\_Tessellate — Perform surface Tessellation of a polygon or polyhedralsurface and returns as a TIN or collection of TINS

#### Synopsis

geometry **ST\_Tessellate**(geometry geom);

#### Description

Takes as input a surface such a MULTI(POLYGON) or POLYHEDRALSURFACE and returns a TIN representation via the process of tessellation using triangles.

Availability: 2.1.0

This method needs SFCGAL backend.

This function supports 3d and will not drop the z-index.

This function supports Polyhedral surfaces.

This function supports Triangles and Triangulated Irregular Network Surfaces (TIN).

## Examples

---

<pre>SELECT ST_GeomFromText('POLYHEDRALSURFACE ↵     Z( ((0 0 0, 0 0 1, 0 1 1, 0 1 0, 0 0 0)), ↵     ((0 0 0, 0 1 0, 1 1 0, 1 0 0, 0 0 0)), ↵     ((1 1 0, 1 1 1, 1 0 1, 1 0 0, 1 1 0)), ↵     ((0 1 0, 0 1 1, 1 1 1, 1 1 0, 0 1 1)), ↵     ((0 0 1, 1 0 1, 1 1 1, 1 0 0, 0 0 0))</pre>	<pre>SELECT ST_Tessellate(ST_GeomFromText(' ↵     POLYHEDRALSURFACE Z( ((0 0 0, 0 ↵     ((0 0 0, 0 1 0, 1 1 0, 1 0 0, 0 0 ↵     ((1 1 0, 1 1 1, 1 0 1, 1 0 0, 1 1 ↵     ((0 1 0, 0 1 1, 1 1 1, 1 1 0, 0 1 ↵     ((0 0 1, 1 0 1, 1 1 1, 1 0 0, 0 0 ↵     ((0 0 0, 0 1 0, 1 1 0, 0 0 0)), ↵     ((1 0 0, 0 0 0, 1 1 0, 1 0 0)), ↵     ((0 0 1, 0 0 0, 1 0 0, 0 0 1)), ↵     ((1 1 0, 1 1 1, 1 0 1, 1 1 0)), ↵     ((0 1 0, 0 1 1, 1 1 1, 0 1 0)), ↵     ((0 1 1, 1 0 1, 1 1 1, 0 1 1)), ↵     ((0 1 0, 0 1 1, 1 1 1, 1 1 0)), ↵     ((0 1 1, 1 0 1, 1 1 1, 0 1 1))</pre>
	
<p><i>Original Cube</i></p>	<p><i>Tessellated Cube with triangles colored</i></p>

<pre>SELECT 'POLYGON (( 10 190, 10 70, 80 70, ↵ 80 130, 50 160, 120 160,</pre>  <p style="text-align: center;"><i>Original polygon</i></p>	<pre>SELECT   ST_Tessellate('POLYGON (( 10 190, ↵ 120 190, 10 190 ))',:geometry; FIN(((80 130,50 160,80 70,80 130)),((50 ↵ 160,10 190,10 70,50 160)), ((80 70,50 160,10 70,80 70)) ↵ ,((120 160,120 190,50 160,120 1 ((120 190,10 190,50 160,120 190)))</pre> <p><b>ST_AsText output</b></p>  <p style="text-align: center;"><i>Tessellated Polygon</i></p>
-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------	-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------

### 8.10.14 ST\_Volume

ST\_Volume — Computes the volume of a 3D solid. If applied to surface (even closed) geometries will return 0.

#### Synopsis

```
float ST_Volume(geometry geom1);
```

#### Description

Availability: 2.2.0

- ✓ This method needs SFCGAL backend.
- ✓ This function supports 3d and will not drop the z-index.
- ✓ This function supports Polyhedral surfaces.
- ✓ This function supports Triangles and Triangulated Irregular Network Surfaces (TIN).

## Example

When closed surfaces are created with WKT, they are treated as areal rather than solid. To make them solid, you need to use [ST\\_MakeSolid](#). Areal geometries have no volume. Here is an example to demonstrate.

```
SELECT ST_Volume(geom) As cube_surface_vol,
 ST_Volume(ST_MakeSolid(geom)) As solid_surface_vol
FROM (SELECT 'POLYHEDRALSURFACE(((0 0 0, 0 0 1, 0 1 1, 0 1 0, 0 0 0)),
 ((0 0 0, 0 1 0, 1 1 0, 1 0 0, 0 0 0)),
 ((0 0 0, 1 0 0, 1 0 1, 0 0 1, 0 0 0)),
 ((1 1 0, 1 1 1, 1 0 1, 1 0 0, 1 1 0)),
 ((0 1 0, 0 1 1, 1 1 1, 1 1 0, 0 1 0)),
 ((0 0 1, 1 0 1, 1 1 1, 0 1 1, 0 0 1)))'::geometry) As f(geom);
```

cube_surface_vol	solid_surface_vol
0	1

## See Also

### 8.10.15 ST\_MakeSolid

**ST\_MakeSolid** — Cast the geometry into a solid. No check is performed. To obtain a valid solid, the input geometry must be a closed Polyhedral Surface or a closed TIN.

#### Synopsis

```
geometry ST_MakeSolid(geometry geom1);
```

#### Description

Availability: 2.2.0

This method needs SFCGAL backend.

This function supports 3d and will not drop the z-index.

This function supports Polyhedral surfaces.

This function supports Triangles and Triangulated Irregular Network Surfaces (TIN).

### 8.10.16 ST\_IsSolid

**ST\_IsSolid** — Test if the geometry is a solid. No validity check is performed.

#### Synopsis

```
boolean ST_IsSolid(geometry geom1);
```

**Description**

Availability: 2.2.0

This method needs SFCGAL backend.

This function supports 3d and will not drop the z-index.

This function supports Polyhedral surfaces.

This function supports Triangles and Triangulated Irregular Network Surfaces (TIN).

## 8.11 Geometry Processing

### 8.11.1 ST\_Buffer

`ST_Buffer` — (T) Returns a geometry covering all points within a given distance from the input geometry.

**Synopsis**

```
geometry ST_Buffer(geometry g1, float radius_of_buffer);
geometry ST_Buffer(geometry g1, float radius_of_buffer, integer num_seg_quarter_circle);
geometry ST_Buffer(geometry g1, float radius_of_buffer, text buffer_style_parameters);
geography ST_Buffer(geography g1, float radius_of_buffer_in_meters);
geography ST_Buffer(geography g1, float radius_of_buffer, integer num_seg_quarter_circle);
geography ST_Buffer(geography g1, float radius_of_buffer, text buffer_style_parameters);
```

**Description**

Returns a geometry/geography that represents all points whose distance from this Geometry/geography is less than or equal to distance.

Geometry: Calculations are in the Spatial Reference System of the geometry. Introduced in 1.5 support for different end cap and mitre settings to control shape.

**Note**

Negative radii: For polygons, a negative radius can be used, which will shrink the polygon rather than expanding it.

**Note**

Geography: For geography this is really a thin wrapper around the geometry implementation. It first determines the best SRID that fits the bounding box of the geography object (favoring UTM, Lambert Azimuthal Equal Area (LAEA) north/south pole, and falling back on mercator in worst case scenario) and then buffers in that planar spatial ref and retransforms back to WGS84 geography.

For geography this may not behave as expected if object is sufficiently large that it falls between two UTM zones or crosses the dateline

Availability: 1.5 - `ST_Buffer` was enhanced to support different endcaps and join types. These are useful for example to convert road linestrings into polygon roads with flat or square edges instead of rounded edges. Thin wrapper for geography was added. - requires GEOS >= 3.2 to take advantage of advanced geometry functionality.

The optional third parameter (currently only applies to geometry) can either specify number of segments used to approximate a quarter circle (integer case, defaults to 8) or a list of blank-separated key=value pairs (string case) to tweak operations as follows:

- `'quad_segs=#'` : number of segments used to approximate a quarter circle (defaults to 8).
- `'endcap=round|flat|square'` : endcap style (defaults to "round", needs GEOS-3.2 or higher for a different value). 'butt' is also accepted as a synonym for 'flat'.
- `'join=round|mitre|bevel'` : join style (defaults to "round", needs GEOS-3.2 or higher for a different value). 'miter' is also accepted as a synonym for 'mitre'.
- `'mitre_limit=#.#'` : mitre ratio limit (only affects mitered join style). 'miter\_limit' is also accepted as a synonym for 'mitre\_limit'.

Units of radius are measured in units of the spatial reference system.

The inputs can be POINTS, MULTIPOINTS, LINESTRINGS, MULTILINESTRINGS, POLYGONS, MULTIPOLYGONS, and GeometryCollections.

**Note**

This function ignores the third dimension (z) and will always give a 2-d buffer even when presented with a 3d-geometry.

---

Performed by the GEOS module.

This method implements the [OpenGIS Simple Features Implementation Specification for SQL 1.1](#). s2.1.1.3

This method implements the SQL/MM specification. SQL-MM 3: 5.1.17

**Note**

People often make the mistake of using this function to try to do radius searches. Creating a buffer to to a radius search is slow and pointless. Use `ST_DWithin` instead.

---

## Examples

---

*quad\_segs=8 (default)*

```
SELECT ST_Buffer(
 ST_GeomFromText('POINT(100 90)'),
 50, 'quad_segs=8');
```

*quad\_segs=2 (lame)*

```
SELECT ST_Buffer(
 ST_GeomFromText('POINT(100 90)'),
 50, 'quad_segs=2');
```

*endcap=round join=round (default)*

```
SELECT ST_Buffer(
 ST_GeomFromText(
 'LINESTRING(50 50,150 150,150 50)'
), 10, 'endcap=round join=round');
```

*endcap=square*

```
SELECT ST_Buffer(
 ST_GeomFromText(
 'LINESTRING(50 50,150 150,150 50)'
), 10, 'endcap=square join=round');
```

```
--A buffered point approximates a circle
-- A buffered point forcing approximation of (see diagram)
-- 2 points per circle is poly with 8 sides (see diagram)

## 8.11.2 ST\_BuildArea

ST\_BuildArea — Creates an areal geometry formed by the constituent linework of given geometry

### Synopsis

geometry **ST\_BuildArea**(geometry A);

### Description

Creates an areal geometry formed by the constituent linework of given geometry. The return type can be a Polygon or Multi-Polygon, depending on input. If the input lineworks do not form polygons NULL is returned. The inputs can be LINESTRINGS, MULTILINESTRINGS, POLYGONS, MULTIPOLYGONS, and GeometryCollections.

This function will assume all inner geometries represent holes

#### Note

Input linework must be correctly noded for this function to work properly

Availability: 1.1.0 - requires GEOS >= 2.1.0.

### Examples

*This will create a donut*

```
SELECT ST_BuildArea(ST_Collect(smallc,bigc))
FROM (SELECT
 ST_Buffer(
 ST_GeomFromText('POINT(100 90)'), 25) As smallc,
 ST_Buffer(ST_GeomFromText('POINT(100 90)'), 50) As bigc) As foo;
```

*This will create a gaping hole inside the circle with prongs sticking out*

```
SELECT ST_BuildArea(ST_Collect(line,circle))
FROM (SELECT
 ST_Buffer(
 ST_MakeLine(ST_MakePoint(10, 10),ST_MakePoint(190, 190)),
 5) As line,
 ST_Buffer(ST_GeomFromText('POINT(100 90)'), 50) As circle) As foo;

--this creates the same gaping hole
--but using linestrings instead of polygons
SELECT ST_BuildArea(
 ST_Collect(ST_ExteriorRing(line),ST_ExteriorRing(circle))
)
FROM (SELECT ST_Buffer(
 ST_MakeLine(ST_MakePoint(10, 10),ST_MakePoint(190, 190))
 ,5) As line,
 ST_Buffer(ST_GeomFromText('POINT(100 90)'), 50) As circle) As foo;
```

### 8.11.3 ST\_ClipByBox2D

`ST_ClipByBox2D` — Returns the portion of a geometry falling within a rectangle.

#### Synopsis

geometry `ST_ClipByBox2D`(geometry geom, box2d box);

## Description

Clips a geometry by a 2D box in a fast but possibly dirty way. The output geometry is not guaranteed to be valid (self-intersections for a polygon may be introduced). Topologically invalid input geometries do not result in exceptions being thrown.

Performed by the GEOS module.

### Note

Requires GEOS 3.5.0+

Availability: 2.2.0 - requires GEOS >= 3.5.0.

## Examples

```
-- Rely on implicit cast from geometry to box2d for the second parameter
SELECT ST_ClipByBox2D(the_geom, ST_MakeEnvelope(0,0,10,10)) FROM mytab;
```

## See Also

## 8.11.4 ST\_Collect

`ST_Collect` — Return a specified `ST_Geometry` value from a collection of other geometries.

## Synopsis

```
geometry ST_Collect(geometry set g1field);
geometry ST_Collect(geometry g1, geometry g2);
geometry ST_Collect(geometry[] g1_array);
```

## Description

Output type can be a `MULTI*` or a `GEOMETRYCOLLECTION`. Comes in 2 variants. Variant 1 collects 2 geometries. Variant 2 is an aggregate function that takes a set of geometries and collects them into a single `ST_Geometry`.

Aggregate version: This function returns a `GEOMETRYCOLLECTION` or a `MULTI` object from a set of geometries. The `ST_Collect()` function is an "aggregate" function in the terminology of PostgreSQL. That means that it operates on rows of data, in the same way the `SUM()` and `AVG()` functions do. For example, "`SELECT ST_Collect(GEOM) FROM GEOMTABLE GROUP BY ATTRCOLUMN`" will return a separate `GEOMETRYCOLLECTION` for each distinct value of `ATTRCOLUMN`.

Non-Aggregate version: This function returns a geometry being a collection of two input geometries. Output type can be a `MULTI*` or a `GEOMETRYCOLLECTION`.

### Note

`ST_Collect` and `ST_Union` are often interchangeable. `ST_Collect` is in general orders of magnitude faster than `ST_Union` because it does not try to dissolve boundaries or validate that a constructed `MultiPolygon` doesn't have overlapping regions. It merely rolls up single geometries into `MULTI` and `MULTI` or mixed geometry types into `Geometry Collections`. Unfortunately geometry collections are not well-supported by GIS tools. To prevent `ST_Collect` from returning a `Geometry Collection` when collecting `MULTI` geometries, one can use the below trick that utilizes [ST\\_Dump](#) to expand the `MULTI`s out to singles and then regroup them.

Availability: 1.4.0 - ST\_Collect(geomarray) was introduced. ST\_Collect was enhanced to handle more geometries faster.

This function supports 3d and will not drop the z-index.

This method supports Circular Strings and Curves This method supports Circular Strings and Curves, but will never return a MULTICURVE or MULTI as one would expect and PostGIS does not currently support those.

## Examples

Aggregate example (<http://postgis.refrations.net/pipermail/postgis-users/2008-June/020331.html>)

```
SELECT stusps,
 ST_Multi(ST_Collect(f.the_geom)) as singlegeom
FROM (SELECT stusps, (ST_Dump(the_geom)).geom As the_geom
 FROM
 somestatetable) As f
GROUP BY stusps
```

## Non-Aggregate example

```
SELECT ST_AsText(ST_Collect(ST_GeomFromText('POINT(1 2)'),
 ST_GeomFromText('POINT(-2 3)')));

st_astext

MULTIPOINT(1 2,-2 3)

--Collect 2 d points
SELECT ST_AsText(ST_Collect(ST_GeomFromText('POINT(1 2)'),
 ST_GeomFromText('POINT(1 2)')));

st_astext

MULTIPOINT(1 2,1 2)

--Collect 3d points
SELECT ST_AsEWKT(ST_Collect(ST_GeomFromEWKT('POINT(1 2 3)'),
 ST_GeomFromEWKT('POINT(1 2 4)')));

st_asewkt

MULTIPOINT(1 2 3,1 2 4)

--Example with curves
SELECT ST_AsText(ST_Collect(ST_GeomFromText('CIRCULARSTRING(220268 150415,220227 150505,220227 150406)'),
 ST_GeomFromText('CIRCULARSTRING(220227 150406,220227 150407,220227 150406)')));

st_astext

GEOMETRYCOLLECTION(CIRCULARSTRING(220268 150415,220227 150505,220227 150406),
 CIRCULARSTRING(220227 150406,220227 150407,220227 150406))

--New ST_Collect array construct
SELECT ST_Collect(ARRAY(SELECT the_geom FROM sometable));

SELECT ST_AsText(ST_Collect(ARRAY[ST_GeomFromText('LINESTRING(1 2, 3 4)'),
 ST_GeomFromText('LINESTRING(3 4, 4 5)')])) As wktcollect;

--wkt collect --
MULTILINESTRING((1 2,3 4),(3 4,4 5))
```

### 8.11.5 ST\_ConcaveHull

`ST_ConcaveHull` — The concave hull of a geometry represents a possibly concave geometry that encloses all geometries within the set. You can think of it as shrink wrapping.

#### Synopsis

```
geometry ST_ConcaveHull(geometry geomA, float target_percent, boolean allow_holes=false);
```

#### Description

The concave hull of a geometry represents a possibly concave geometry that encloses all geometries within the set. Defaults to false for allowing polygons with holes. The result is never higher than a single polygon.

The `target_percent` is the target percent of area of convex hull the PostGIS solution will try to approach before giving up or exiting. One can think of the concave hull as the geometry you get by vacuum sealing a set of geometries. The `target_percent` of 1 will give you the same answer as the convex hull. A `target_percent` between 0 and 0.99 will give you something that should have a smaller area than the convex hull. This is different from a convex hull which is more like wrapping a rubber band around the set of geometries.

It is usually used with MULTI and Geometry Collections. Although it is not an aggregate - you can use it in conjunction with `ST_Collect` or `ST_Union` to get the concave hull of a set of points/linestring/polygons `ST_ConcaveHull(ST_Collect(somepointfield), 0.80)`.

It is much slower to compute than convex hull but encloses the geometry better and is also useful for image recognition.

Performed by the GEOS module

#### Note

Note - If you are using with points, linestrings, or geometry collections use `ST_Collect`. If you are using with polygons, use `ST_Union` since it may fail with invalid geometries.

#### Note

Note - The smaller you make the target percent, the longer it takes to process the concave hull and more likely to run into topological exceptions. Also the more floating points and number of points you accrue. First try a 0.99 which does a first hop, is usually very fast, sometimes as fast as computing the convex hull, and usually gives much better than 99% of shrink since it almost always overshoots. Second hope of 0.98 it slower, others get slower usually quadratically. To reduce precision and float points, use `ST_SimplifyPreserveTopology` or `ST_SnapToGrid` after `ST_ConcaveHull`. `ST_SnapToGrid` is a bit faster, but could result in invalid geometries where as `ST_SimplifyPreserveTopology` almost always preserves the validity of the geometry.

More real world examples and brief explanation of the technique are shown [http://www.bostongis.com/postgis\\_concavehull.snippet](http://www.bostongis.com/postgis_concavehull.snippet)

Also check out Simon Greener's article on demonstrating ConcaveHull introduced in Oracle 11G R2. [http://www.spatialdbadvisor.com/oracle\\_spatial\\_tips\\_tricks/172/concave-hull-geometries-in-oracle-11gr2](http://www.spatialdbadvisor.com/oracle_spatial_tips_tricks/172/concave-hull-geometries-in-oracle-11gr2). The solution we get at 0.75 target percent of convex hull is similar to the shape Simon gets with Oracle `SDO_CONCAVEHULL_BOUNDARY`.

Availability: 2.0.0

## Examples

```
--Get estimate of infected area based on point observations

### 8.11.6 ST\_ConvexHull

`ST_ConvexHull` — The convex hull of a geometry represents the minimum convex geometry that encloses all geometries within the set.

#### Synopsis

```
geometry ST_ConvexHull(geometry geomA);
```

#### Description

The convex hull of a geometry represents the minimum convex geometry that encloses all geometries within the set.

One can think of the convex hull as the geometry you get by wrapping an elastic band around a set of geometries. This is different from a concave hull which is analogous to shrink-wrapping your geometries.

It is usually used with MULTI and Geometry Collections. Although it is not an aggregate - you can use it in conjunction with `ST_Collect` to get the convex hull of a set of points. `ST_ConvexHull(ST_Collect(somepointfield))`.

It is often used to determine an affected area based on a set of point observations.

Performed by the GEOS module

This method implements the [OpenGIS Simple Features Implementation Specification for SQL 1.1](#). s2.1.1.3

This method implements the SQL/MM specification. SQL-MM 3: 5.1.16

This function supports 3d and will not drop the z-index.

#### Examples

```
--Get estimate of infected area based on point observations
SELECT d.disease_type,
 ST_ConvexHull(ST_Collect(d.the_geom)) As the_geom
FROM disease_obs As d
GROUP BY d.disease_type;
```

*Convex Hull of a MultiLineString and a MultiPoint seen together with the MultiLineString and MultiPoint*

```
SELECT ST_AsText(ST_ConvexHull(
 ST_Collect(
 ST_GeomFromText('MULTILINESTRING((100 190,10 8),(150 10, 20 30)'),
 ST_GeomFromText('MULTIPOINT(50 5, 150 30, 50 10, 10 10)')
)));
---st_astext---
POLYGON((50 5,10 8,10 10,100 190,150 30,150 10,50 5))
```

### 8.11.7 ST\_CurveToLine

`ST_CurveToLine` — Converts a CIRCULARSTRING/CURVEPOLYGON to a LINESTRING/POLYGON

#### Synopsis

```
geometry ST_CurveToLine(geometry curveGeom);
geometry ST_CurveToLine(geometry curveGeom, integer segments_per_qtr_circle);
```

#### Description

Convert a CIRCULAR STRING to regular LINESTRING or CURVEPOLYGON to POLYGON. Useful for outputting to devices that can't support CIRCULARSTRING geometry types

Converts a given geometry to a linear geometry. Each curved geometry or segment is converted into a linear approximation using the default value of 32 segments per quarter circle

Availability: 1.2.2?

This method implements the [OpenGIS Simple Features Implementation Specification for SQL 1.1](#).

This method implements the SQL/MM specification. SQL-MM 3: 7.1.7

This function supports 3d and will not drop the z-index.

This method supports Circular Strings and Curves

## Examples

```
SELECT ST_AsText(ST_CurveToLine(ST_GeomFromText('CIRCULARSTRING(220268 150415,220227 150505,220227 150406)')));
```

```

**See Also**[ST\\_LineToCurve](#)**8.11.8 ST\_DelaunayTriangles**

`ST_DelaunayTriangles` — Return a Delaunay triangulation around the given input points.

**Synopsis**

```
geometry ST_DelaunayTriangles(geometry g1, float tolerance, int4 flags);
```

**Description**

Return a **Delaunay triangulation** around the vertices of the input geometry. Output is a **COLLECTION** of polygons (for flags=0) or a **MULTILINESTRING** (for flags=1) or **TIN** (for flags=2). The tolerance, if any, is used to snap input vertices together.

Availability: 2.1.0 - requires GEOS >= 3.4.0.

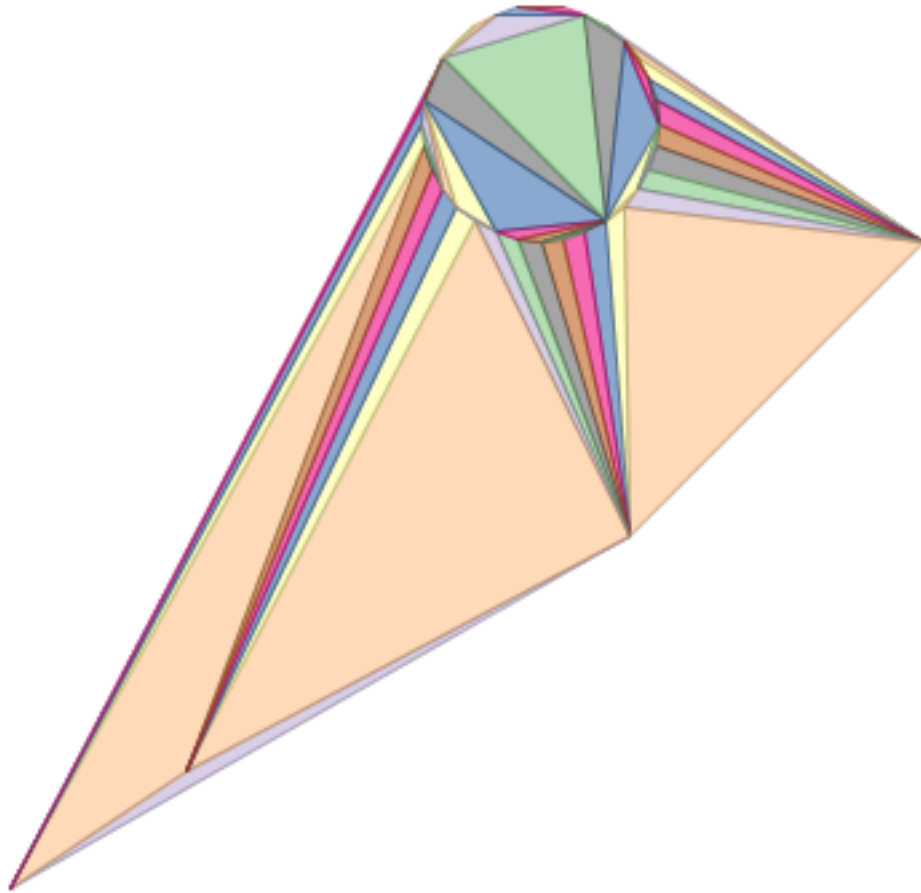

This function supports 3d and will not drop the z-index.

This function supports Triangles and Triangulated Irregular Network Surfaces (TIN).

## 2D Examples

*ST\_DelaunayTriangles of 2 polygons: delaunay triangle polygons each triangle themed in different color*

```
-- geometries overlaid multilinestring triangles
SELECT
 ST_DelaunayTriangles(

**8.11.9 ST\_Difference**

`ST_Difference` — Returns a geometry that represents that part of geometry A that does not intersect with geometry B.

**Synopsis**

```
geometry ST_Difference(geometry geomA, geometry geomB);
```

**Description**

Returns a geometry that represents that part of geometry A that does not intersect with geometry B. One can think of this as  $\text{GeometryA} - \text{ST\_Intersection}(A,B)$ . If A is completely contained in B then an empty geometry collection is returned.

**Note**

Note - order matters. B - A will always return a portion of B

Performed by the GEOS module

**Note**

Do not call with a GeometryCollection as an argument

This method implements the [OpenGIS Simple Features Implementation Specification for SQL 1.1](#). s2.1.1.3

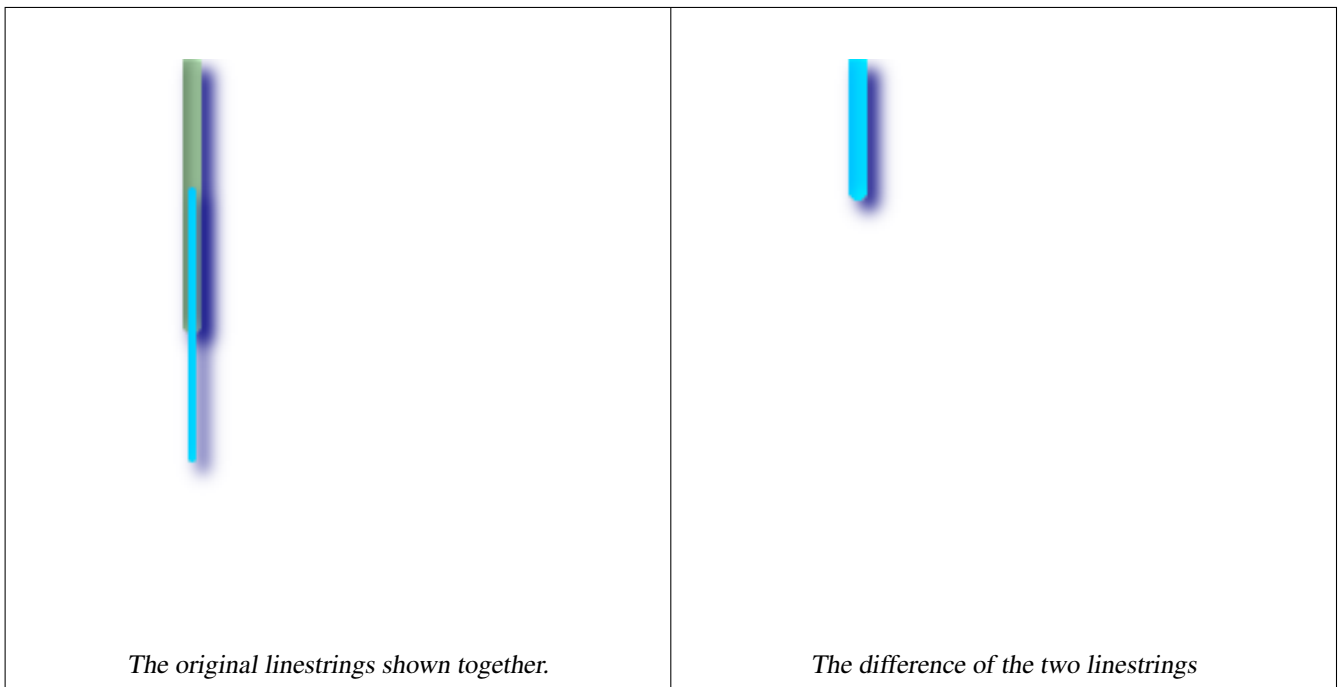

This method implements the SQL/MM specification. SQL-MM 3: 5.1.20

This function supports 3d and will not drop the z-index. However it seems to only consider x y when doing the difference and tacks back on the Z-Index

**Examples**

```
--Safe for 2d. This is same geometries as what is shown for st_symdifference
SELECT ST_AsText(
 ST_Difference(
 ST_GeomFromText('LINESTRING(50 100, 50 200)'),
 ST_GeomFromText('LINESTRING(50 50, 50 150)')
)
);

st_astext

LINESTRING(50 150,50 200)
```

```
--When used in 3d doesn't quite do the right thing
SELECT ST_AsEWKT(ST_Difference(ST_GeomFromEWKT('MULTIPOINT(-118.58 38.38 5,-118.60 38.329 6,-118.614 38.281 7)'), ST_GeomFromEWKT('POINT(-118.614 38.281 5)')));
st_asewkt

MULTIPOINT(-118.6 38.329 6,-118.58 38.38 5)
```

### 8.11.10 ST\_Dump

**ST\_Dump** — Returns a set of `geometry_dump` (geom,path) rows, that make up a geometry `g1`.

#### Synopsis

```
geometry_dump[] ST_Dump(geometry g1);
```

## Description

This is a set-returning function (SRF). It returns a set of `geometry_dump` rows, formed by a geometry (`geom`) and an array of integers (`path`). When the input geometry is a simple type (`POINT`,`LINESTRING`,`POLYGON`) a single record will be returned with an empty path array and the input geometry as `geom`. When the input geometry is a collection or multi it will return a record for each of the collection components, and the path will express the position of the component inside the collection.

`ST_Dump` is useful for expanding geometries. It is the reverse of a `GROUP BY` in that it creates new rows. For example it can be used to expand `MULTIPOLYGONS` into `POLYGONS`.

Enhanced: 2.0.0 support for Polyhedral surfaces, Triangles and TIN was introduced.

Availability: PostGIS 1.0.0RC1. Requires PostgreSQL 7.3 or higher.

### Note

Prior to 1.3.4, this function crashes if used with geometries that contain `CURVES`. This is fixed in 1.3.4+

This method supports Circular Strings and Curves

This function supports Polyhedral surfaces.

This function supports Triangles and Triangulated Irregular Network Surfaces (TIN).

This function supports 3d and will not drop the z-index.

## Standard Examples

```
SELECT sometable.field1, sometable.field1,
 (ST_Dump(sometable.the_geom)).geom AS the_geom
FROM sometable;

-- Break a compound curve into its constituent linestrings and circularstrings
SELECT ST_AsEWKT(a.geom), ST_HasArc(a.geom)
FROM (SELECT (ST_Dump(p_geom)).geom AS geom
 FROM (SELECT ST_GeomFromEWKT('COMPOUNDCURVE(CIRCULARSTRING(0 0, 1 1, 1 0),(1 0, 0
1))') AS p_geom) AS b
) AS a;

### 8.11.11 ST\_DumpPoints

**ST\_DumpPoints** — Returns a set of `geometry_dump` (`geom,path`) rows of all points that make up a geometry.

#### Synopsis

```
geometry_dump[]ST_DumpPoints(geometry geom);
```

#### Description

This set-returning function (SRF) returns a set of `geometry_dump` rows formed by a geometry (`geom`) and an array of integers (`path`).

The `geom` component of `geometry_dump` are all the POINTs that make up the supplied geometry

The `path` component of `geometry_dump` (an `integer[]`) is an index reference enumerating the POINTs of the supplied geometry. For example, if a `LINestring` is supplied, a path of `{i}` is returned where `i` is the `n`th coordinate in the `LINestring`. If a `POLYGON` is supplied, a path of `{i, j}` is returned where `i` is the ring number (1 is outer; inner rings follow) and `j` enumerates the POINTs (again 1-based index).

Enhanced: 2.1.0 Faster speed. Reimplemented as native-C.

Enhanced: 2.0.0 support for Polyhedral surfaces, Triangles and TIN was introduced.

Availability: 1.5.0

- ✓ This method supports Circular Strings and Curves
- ✓ This function supports Polyhedral surfaces.
- ✓ This function supports Triangles and Triangulated Irregular Network Surfaces (TIN).
- ✓ This function supports 3d and will not drop the z-index.

[geometry\\_dump](#), Section 14.6, [ST\\_Dump](#), [ST\\_DumpRings](#)

**8.11.12 ST\_DumpRings**

**ST\_DumpRings** — Returns a set of `geometry_dump` rows, representing the exterior and interior rings of a polygon.

**Synopsis**

```
geometry_dump[] ST_DumpRings(geometry a_polygon);
```

**Description**

This is a set-returning function (SRF). It returns a set of `geometry_dump` rows, defined as an `integer[]` and a `geometry`, aliased "path" and "geom" respectively. The "path" field holds the polygon ring index containing a single integer: 0 for the shell, >0 for holes. The "geom" field contains the corresponding ring as a polygon.

Availability: PostGIS 1.1.3. Requires PostgreSQL 7.3 or higher.

**Note**

This only works for POLYGON geometries. It will not work for MULTIPOLYGONS

This function supports 3d and will not drop the z-index.

## Examples

```
SELECT sometable.field1, sometable.field1,
 (ST_DumpRings(sometable.the_geom)).geom As the_geom
FROM sometableOfpolys;

SELECT ST_AsEWKT(geom) As the_geom, path
FROM ST_DumpRings(
 ST_GeomFromEWKT('POLYGON((-8149064 5133092 1,-8149064 5132986 1,-8148996 5132839 ↵

### 8.11.13 ST\_FlipCoordinates

**ST\_FlipCoordinates** — Returns a version of the given geometry with X and Y axis flipped. Useful for people who have built latitude/longitude features and need to fix them.

#### Synopsis

```
geometry ST_FlipCoordinates(geometry geom);
```

#### Description

Returns a version of the given geometry with X and Y axis flipped.

Availability: 2.0.0

This method supports Circular Strings and Curves

This function supports 3d and will not drop the z-index.

This function supports M coordinates.

This function supports Polyhedral surfaces.

This function supports Triangles and Triangulated Irregular Network Surfaces (TIN).

### Example

```
SELECT ST_AsEWKT(ST_FlipCoordinates(GeomFromEWKT('POINT(1 2)')));
 st_asewkt

POINT(2 1)
```

### See Also

[ST\\_SwapOrdinates](#)

## 8.11.14 ST\_GeneratePoints

**ST\_GeneratePoints** — Converts a polygon or multi-polygon into a multi-point composed of randomly location points within the original areas.

### Synopsis

geometry **ST\_GeneratePoints**( g geometry , npoints numeric );

### Description

**ST\_GeneratePoints** generates pseudo-random points until the requested number are found within the input area.

Availability: 2.3.0

### Examples

---

### 8.11.15 ST\_Intersection

**ST\_Intersection** — (T) Returns a geometry that represents the shared portion of geomA and geomB.

#### Synopsis

```
geometry ST_Intersection(geometry geomA , geometry geomB);
geography ST_Intersection(geography geogA , geography geogB);
```

#### Description

Returns a geometry that represents the point set intersection of the Geometries.

In other words - that portion of geometry A and geometry B that is shared between the two geometries.

If the geometries do not share any space (are disjoint), then an empty geometry collection is returned.

**ST\_Intersection** in conjunction with **ST\_Intersects** is very useful for clipping geometries such as in bounding box, buffer, region queries where you only want to return that portion of a geometry that sits in a country or region of interest.

#### Note

Geography: For geography this is really a thin wrapper around the geometry implementation. It first determines the best SRID that fits the bounding box of the 2 geography objects (if geography objects are within one half zone UTM but not same UTM will pick one of those) (favoring UTM or Lambert Azimuthal Equal Area (LAEA) north/south pole, and falling back on mercator in worst case scenario) and then intersection in that best fit planar spatial ref and retransforms back to WGS84 geography.

**Important**

Do not call with a `GEOMETRYCOLLECTION` as an argument

**Warning**

This function will drop the M coordinate values if present.

**Warning**

If working with 3D geometries, you may want to use SFCGAL based `ST_3DIntersection` which does a proper 3D intersection for 3D geometries. Although this function works with Z-coordinate, it does an averaging of Z-Coordinate values when `postgis.backend=geos`. `postgis.backend=sfcgal`, it will return a 2D geometry regardless ignoring the Z-Coordinate. Refer to `postgis.backend` for details.

Performed by the GEOS module

This method is also provided by SFCGAL backend.

Availability: 1.5 support for geography data type was introduced.

This method implements the [OpenGIS Simple Features Implementation Specification for SQL 1.1](#). s2.1.1.3

This method implements the SQL/MM specification. SQL-MM 3: 5.1.18

**Examples**

```
SELECT ST_AsText(ST_Intersection('POINT(0 0)::geometry, 'LINESTRING (2 0, 0 2)':: ←
 geometry));
st_astext

GEOMETRYCOLLECTION EMPTY
(1 row)
SELECT ST_AsText(ST_Intersection('POINT(0 0)::geometry, 'LINESTRING (0 0, 0 2)':: ←
 geometry));
st_astext

POINT(0 0)
(1 row)

---Clip all lines (trails) by country (here we assume country geom are POLYGON or ←
MULTIPOLYGONS)
-- NOTE: we are only keeping intersections that result in a LINESTRING or MULTILINESTRING ←
because we don't
-- care about trails that just share a point
-- the dump is needed to expand a geometry collection into individual single MULT* parts
-- the below is fairly generic and will work for polys, etc. by just changing the where ←
clause
SELECT clipped.gid, clipped.f_name, clipped_geom
FROM (SELECT trails.gid, trails.f_name, (ST_Dump(ST_Intersection(country.the_geom, trails. ←
 the_geom))).geom As clipped_geom
FROM country
INNER JOIN trails
```

```

ON ST_Intersects(country.the_geom, trails.the_geom)) As clipped
WHERE ST_Dimension(clipped.clipped_geom) = 1 ;

--For polys e.g. polygon landmarks, you can also use the sometimes faster hack that ↔
 buffering anything by 0.0
-- except a polygon results in an empty geometry collection
--(so a geometry collection containing polys, lines and points)
-- buffered by 0.0 would only leave the polygons and dissolve the collection shell
SELECT poly.gid, ST_Multi(ST_Buffer(
 ST_Intersection(country.the_geom, poly.the_geom),
 0.0)
) As clipped_geom
FROM country
 INNER JOIN poly
 ON ST_Intersects(country.the_geom, poly.the_geom)
 WHERE Not ST_IsEmpty(ST_Buffer(ST_Intersection(country.the_geom, poly.the_geom),0.0));

```

### Examples: 2.5Dish

Geos is the default backend if not set. Note this is not a true intersection, compare to the same example using [ST\\_3DIntersection](#).

```

set postgis.backend=geos;
select ST_AsText(ST_Intersection(linestring, polygon)) As wkt
from ST_GeomFromText('LINESTRING Z (2 2 6,1.5 1.5 7,1 1 8,0.5 0.5 8,0 0 10)') AS ↔
 linestring
 CROSS JOIN ST_GeomFromText('POLYGON((0 0 8, 0 1 8, 1 1 8, 1 0 8, 0 0 8))') AS polygon;

 st_astext

LINESTRING Z (1 1 8,0.5 0.5 8,0 0 10)

```

If your PostGIS is compiled with sfcgal support, have option of using sfcgal, but note if basically cases down both geometries to 2D before doing intersection and returns the `ST_Force2D` equivalent result which is a 2D geometry

```

set postgis.backend=sfcgal;
select ST_AsText(ST_Intersection(linestring, polygon)) As wkt
from ST_GeomFromText('LINESTRING Z (2 2 6,1.5 1.5 7,1 1 8,0.5 0.5 8,0 0 10)') AS ↔
 linestring
 CROSS JOIN ST_GeomFromText('POLYGON((0 0 8, 0 1 8, 1 1 8, 1 0 8, 0 0 8))') AS polygon;

 wkt

MULTILINESTRING((0.5 0.5,0 0),(1 1,0.5 0.5))

```

### 8.11.16 ST\_LineToCurve

`ST_LineToCurve` — Converts a `LINESTRING`/`POLYGON` to a `CIRCULARSTRING`, `CURVEPOLYGON`

#### Synopsis

geometry `ST_LineToCurve`(geometry geomANoncircular);

### Description

Converts plain LINESTRING/POLYGON to CIRCULAR STRINGS and Curved Polygons. Note much fewer points are needed to describe the curved equivalent.

**Note**

If the input LINESTRING/POLYGON is not curved enough to clearly represent a curve, the function will return the same input geometry.

Availability: 1.2.2?

This function supports 3d and will not drop the z-index.

This method supports Circular Strings and Curves

### Examples

```
-- 2D Example
SELECT ST_AsText(ST_LineToCurve(foo.the_geom)) As curvedastext,ST_AsText(foo.the_geom) As
 non_curvedastext
 FROM (SELECT ST_Buffer('POINT(1 3)::geometry, 3) As the_geom) As foo;
```

```

**See Also**[ST\\_CurveToLine](#)**8.11.17 ST\_MakeValid**

`ST_MakeValid` — Attempts to make an invalid geometry valid without losing vertices.

**Synopsis**

geometry `ST_MakeValid`(geometry input);

**Description**

The function attempts to create a valid representation of a given invalid geometry without losing any of the input vertices. Already-valid geometries are returned without further intervention.

Supported inputs are: POINTS, MULTIPOINTS, LINESTRINGS, MULTILINESTRINGS, POLYGONS, MULTIPOLYGONS and GEOMETRYCOLLECTIONS containing any mix of them.

In case of full or partial dimensional collapses, the output geometry may be a collection of lower-to-equal dimension geometries or a geometry of lower dimension.

Single polygons may become multi-geometries in case of self-intersections.

Availability: 2.0.0, requires GEOS-3.3.0

Enhanced: 2.0.1, speed improvements requires GEOS-3.3.4

Enhanced: 2.1.0 added support for GEOMETRYCOLLECTION and MULTIPOINT.

This function supports 3d and will not drop the z-index.

**See Also**[ST\\_IsValid](#) [ST\\_CollectionExtract](#)**8.11.18 ST\_MemUnion**

`ST_MemUnion` — Same as `ST_Union`, only memory-friendly (uses less memory and more processor time).

**Synopsis**

geometry `ST_MemUnion`(geometry set geomfield);

## Description

Some useful description here.

### Note

Same as `ST_Union`, only memory-friendly (uses less memory and more processor time). This aggregate function works by unioning the geometries one at a time to previous result as opposed to `ST_Union` aggregate which first creates an array and then unions

This function supports 3d and will not drop the z-index.

## Examples

See `ST_Union`

## See Also

[ST\\_Union](#)

## 8.11.19 ST\_MinimumBoundingCircle

`ST_MinimumBoundingCircle` — Returns the smallest circle polygon that can fully contain a geometry. Default uses 48 segments per quarter circle.

## Synopsis

```
geometry ST_MinimumBoundingCircle(geometry geomA, integer num_segs_per_qt_circ=48);
```

## Description

Returns the smallest circle polygon that can fully contain a geometry.

### Note

The circle is approximated by a polygon with a default of 48 segments per quarter circle. Because the polygon is an approximation of the minimum bounding circle, some points in the input geometry may not be contained within the polygon. The approximation can be improved by increasing the number of segments, with little performance penalty. For applications where a polygonal approximation is not suitable, `ST_MinimumBoundingRadius` may be used.

It is often used with `MULTI` and Geometry Collections. Although it is not an aggregate - you can use it in conjunction with `ST_Collect` to get the minimum bounding circle of a set of geometries. `ST_MinimumBoundingCircle(ST_Collect(somepointfield))`.

The ratio of the area of a polygon divided by the area of its Minimum Bounding Circle is often referred to as the Roeck test.

Availability: 1.4.0 - requires GEOS

### 8.11.20 ST\_MinimumBoundingRadius

ST\_MinimumBoundingRadius — Returns the center point and radius of the smallest circle that can fully contain a geometry.

#### Synopsis

```
(geometry, double precision) ST_MinimumBoundingRadius(geometry geom);
```

#### Description

Returns a record containing the center point and radius of the smallest circle that can fully contain a geometry.

Can be used in conjunction with [ST\\_Collect](#) to get the minimum bounding circle of a set of geometries.

Availability - 2.3.0

#### See Also

[ST\\_Collect](#), [ST\\_MinimumBoundingCircle](#)

#### Examples

```
SELECT ST_AsText(center), radius FROM ST_MinimumBoundingRadius('POLYGON((26426 65078,26531 ←
 65242,26075 65136,26096 65427,26426 65078))');
```

st_astext	radius

### 8.11.21 ST\_Polygonize

ST\_Polygonize — Aggregate. Creates a GeometryCollection containing possible polygons formed from the constituent linework of a set of geometries.

#### Synopsis

```
geometry ST_Polygonize(geometry set geomfield);
geometry ST_Polygonize(geometry[] geom_array);
```

#### Description

Creates a GeometryCollection containing possible polygons formed from the constituent linework of a set of geometries.

#### Note

Geometry Collections are often difficult to deal with with third party tools, so use ST\_Polygonize in conjunction with [ST\\_Dump](#) to dump the polygons out into individual polygons.

#### Note

Input linework must be correctly noded for this function to work properly

Availability: 1.0.0RC1 - requires GEOS >= 2.1.0.

**Examples: Polygonizing single linestrings**

```

SELECT ST_AsEWKT(ST_Polygonize(the_geom_4269)) As geomtextrep
FROM (SELECT the_geom_4269 FROM ma.suffolk_edges ORDER BY tlid LIMIT 45) As foo;

geomtextrep

POLYGON((-71.17166 42.353675,-71.172026 42.354044,-71.17239 42.354358,-71.171794 42.354971,-71.170511 42.354855,
-71.17112 42.354238,-71.17166 42.353675)))
(1 row)

--Use ST_Dump to dump out the polygonize geoms into individual polygons
SELECT ST_AsEWKT((ST_Dump(foofoo.polycoll)).geom) As geomtextrep
FROM (SELECT ST_Polygonize(the_geom_4269) As polycoll
 FROM (SELECT the_geom_4269 FROM ma.suffolk_edges
 ORDER BY tlid LIMIT 45) As foo) As foofoo;

geomtextrep

SRID=4269;POLYGON((-71.040878 42.285678,-71.040943 42.2856,-71.04096 42.285752,-71.040878 42.285678))
SRID=4269;POLYGON((-71.17166 42.353675,-71.172026 42.354044,-71.17239 42.354358,-71.171794 42.354971,-71.170511 42.354855,-71.17112 42.354238,-71.17166 42.353675))
(2 rows)

```

**See Also**[ST\\_Node](#), [ST\\_Dump](#)**8.11.22 ST\_Node**

ST\_Node — Node a set of linestrings.

**Synopsis**

geometry **ST\_Node**(geometry geom);

**Description**

Fully node a set of linestrings using the least possible number of nodes while preserving all of the input ones.

This function supports 3d and will not drop the z-index.

Availability: 2.0.0 - requires GEOS >= 3.3.0.

**Note**

Due to a bug in GEOS up to 3.3.1 this function fails to node self-intersecting lines. This is fixed with GEOS 3.3.2 or higher.

## Examples

```
SELECT ST_AseWKT(
 ST_Node('LINESTRINGZ(0 0 0, 10 10 10, 0 10 5, 10 0 3)::geometry)
) As output;
output

MULTILINESTRING((0 0 0,5 5 4.5),(5 5 4.5,10 10 10,0 10 5,5 5 4.5),(5 5 4.5,10 0 3))
```

## See Also

[ST\\_UnaryUnion](#)

### 8.11.23 ST\_OffsetCurve

**ST\_OffsetCurve** — Return an offset line at a given distance and side from an input line. Useful for computing parallel lines about a center line

#### Synopsis

geometry **ST\_OffsetCurve**(geometry line, float signed\_distance, text style\_parameters=’');

#### Description

Return an offset line at a given distance and side from an input line. All points of the returned geometries are not further than the given distance from the input geometry.

For positive distance the offset will be at the left side of the input line and retain the same direction. For a negative distance it’ll be at the right side and in the opposite direction.

Availability: 2.0 - requires GEOS >= 3.2, improved with GEOS >= 3.3

The optional third parameter allows specifying a list of blank-separated key=value pairs to tweak operations as follows:

- ‘quad\_segs=#’ : number of segments used to approximate a quarter circle (defaults to 8).
- ‘join=round|mitre|bevel’ : join style (defaults to "round"). ‘miter’ is also accepted as a synonym for ‘mitre’.
- ‘mitre\_limit=#.#’ : mitre ratio limit (only affects mitred join style). ‘miter\_limit’ is also accepted as a synonym for ‘mitre\_limit’.

Units of distance are measured in units of the spatial reference system.

The inputs can only be LINESTRINGS.

Performed by the GEOS module.

#### Note

This function ignores the third dimension (z) and will always give a 2-d result even when presented with a 3d-geometry.

## Examples

### Compute an open buffer around roads

```
SELECT ST_Union(
 ST_OffsetCurve(f.the_geom, f.width/2, 'quad_segs=4 join=round'),
 ST_OffsetCurve(f.the_geom, -f.width/2, 'quad_segs=4 join=round')
) as track
FROM someroadstable;
```

15, 'quad\_segs=4 join=round' original line and its offset 15 units.

```
SELECT ST_AsText(ST_OffsetCurve(↵
 ST_GeomFromText(↵

## 8.11.24 ST\_RemoveRepeatedPoints

`ST_RemoveRepeatedPoints` — Returns a version of the given geometry with duplicated points removed.

### Synopsis

```
geometry ST_RemoveRepeatedPoints(geometry geom, float8 tolerance);
```

### Description

Returns a version of the given geometry with duplicated points removed. Will actually do something only with (multi)lines, (multi)polygons and multipoints but you can safely call it with any kind of geometry. Since simplification occurs on a object-by-

object basis you can also feed a `GeometryCollection` to this function.

If the tolerance parameter is provided, vertices within the tolerance of one another will be considered the "same" for the purposes of removal.

Availability: 2.2.0

This function supports Polyhedral surfaces.

This function supports 3d and will not drop the z-index.

### See Also

[ST\\_Simplify](#)

## 8.11.25 ST\_SharedPaths

`ST_SharedPaths` — Returns a collection containing paths shared by the two input linestrings/multilinestrings.

### Synopsis

```
geometry ST_SharedPaths(geometry lineal1, geometry lineal2);
```

### Description

Returns a collection containing paths shared by the two input geometries. Those going in the same direction are in the first element of the collection, those going in the opposite direction are in the second element. The paths themselves are given in the direction of the first geometry.

Availability: 2.0.0 requires GEOS >= 3.3.0.

### Examples: Finding shared paths

*A multilinestring and a linestring*

*The shared path of multilinestring and linestring overlaid with original geometries.*

```
SELECT ST_AsText (
 ST_SharedPaths (
 ST_GeomFromText ('MULTILINESTRING((26 125,26 200,126 200,126 125,26 125),
 (51 150,101 150,76 175,51 150))'),
 ST_GeomFromText ('LINESTRING(151 100,126 156.25,126 125,90 161, 76 175)')
)
) As wkt
```

wkt

```

GEOMETRYCOLLECTION(MULTILINESTRING((126 156.25,126 125),
(101 150,90 161),(90 161,76 175)),MULTILINESTRING EMPTY)
```

-- same example but linestring orientation flipped

```
SELECT ST_AsText (
 ST_SharedPaths (
 ST_GeomFromText ('LINESTRING(76 175,90 161,126 125,126 156.25,151 100)'),
 ST_GeomFromText ('MULTILINESTRING((26 125,26 200,126 200,126 125,26 125),
 (51 150,101 150,76 175,51 150))')
)
) As wkt
```

wkt

```

GEOMETRYCOLLECTION(MULTILINESTRING EMPTY,
MULTILINESTRING((76 175,90 161),(90 161,101 150),(126 125,126 156.25)))
```

## 8.11.26 ST\_ShiftLongitude

ST\_ShiftLongitude — Toggle geometry coordinates between -180..180 and 0..360 ranges.

### Synopsis

geometry **ST\_ShiftLongitude**(geometry geomA);

### Description

Reads every point/vertex in every component of every feature in a geometry, and if the longitude coordinate is <0, adds 360 to it. The result would be a 0-360 version of the data to be plotted in a 180 centric map

#### Note

This is only useful for data in long lat e.g. 4326 (WGS 84 long lat)

Pre-1.3.4 bug prevented this from working for MULTIPOINT. 1.3.4+ works with MULTIPOINT as well.

This function supports 3d and will not drop the z-index.

Enhanced: 2.0.0 support for Polyhedral surfaces and TIN was introduced.

NOTE: this function was renamed from "ST\_Shift\_Longitude" in 2.2.0

This function supports Polyhedral surfaces.

This function supports Triangles and Triangulated Irregular Network Surfaces (TIN).

### Examples

```
--3d points
SELECT ST_AsEWKT(ST_ShiftLongitude(ST_GeomFromEWKT('SRID=4326;POINT(-118.58 38.38 10)')) ←
 As geomA,
 ST_AsEWKT(ST_ShiftLongitude(ST_GeomFromEWKT('SRID=4326;POINT(241.42 38.38 10)')) As ←
 geomB
geomA geomB

SRID=4326;POINT(241.42 38.38 10) SRID=4326;POINT(-118.58 38.38 10)

--regular line string
SELECT ST_AsText(ST_ShiftLongitude(ST_GeomFromText('LINESTRING(-118.58 38.38, -118.20 ←
 38.45)'))))
st_astext

LINESTRING(241.42 38.38,241.8 38.45)
```

### See Also

[ST\\_WrapX](#)

### 8.11.27 ST\_WrapX

ST\_WrapX — Wrap a geometry around an X value.

#### Synopsis

```
geometry ST_WrapX(geometry geom, float8 wrap, float8 move);
```

#### Description

This function splits the input geometries and then moves every resulting component falling on the right (for negative 'move') or on the left (for positive 'move') of given 'wrap' line in the direction specified by the 'move' parameter, finally re-unioning the pieces together.

#### Note

This is useful to "recenter" long-lat input to have features of interest not spawned from one side to the other.

Availability: 2.3.0

This function supports 3d and will not drop the z-index.

#### Examples

```
-- Move all components of the given geometries whose bounding box
-- falls completely on the left of x=0 to +360
select ST_WrapX(the_geom, 0, 360);

-- Move all components of the given geometries whose bounding box
-- falls completely on the left of x=-30 to +360
select ST_WrapX(the_geom, -30, 360);
```

#### See Also

[ST\\_ShiftLongitude](#)

### 8.11.28 ST\_Simplify

ST\_Simplify — Returns a "simplified" version of the given geometry using the Douglas-Peucker algorithm.

#### Synopsis

```
geometry ST_Simplify(geometry geomA, float tolerance, boolean preserveCollapsed);
```

## Description

Returns a "simplified" version of the given geometry using the Douglas-Peucker algorithm. Will actually do something only with (multi)lines and (multi)polygons but you can safely call it with any kind of geometry. Since simplification occurs on a object-by-object basis you can also feed a `GeometryCollection` to this function.

The "preserve collapsed" flag will retain objects that would otherwise be too small given the tolerance. For example, a 1m long line simplified with a 10m tolerance. If the preserve flag is given, the line will not disappear. This flag is useful for rendering engines, to avoid having large numbers of very small objects disappear from a map leaving surprising gaps.

### Note

Note that returned geometry might lose its simplicity (see [ST\\_IsSimple](#))

### Note

Note topology may not be preserved and may result in invalid geometries. Use (see [ST\\_SimplifyPreserveTopology](#)) to preserve topology.

Availability: 1.2.2

## Examples

A circle simplified too much becomes a triangle, medium an octagon,

```
SELECT ST_Npoints(the_geom) As np_before, ST_NPoints(ST_Simplify(the_geom,0.1)) As ←
 np01_notbadcircle, ST_NPoints(ST_Simplify(the_geom,0.5)) As np05_notquitecircle,
ST_NPoints(ST_Simplify(the_geom,1)) As np1_octagon, ST_NPoints(ST_Simplify(the_geom,10)) As ←
 np10_triangle,
(ST_Simplify(the_geom,100) is null) As np100_geometrygoesaway
FROM (SELECT ST_Buffer('POINT(1 3)', 10,12) As the_geom) As foo;
-result
 np_before | np01_notbadcircle | np05_notquitecircle | np1_octagon | np10_triangle | ←
 np100_geometrygoesaway
-----+-----+-----+-----+-----+-----+-----
 49 | 33 | 17 | 9 | 4 | t
```

## See Also

[ST\\_IsSimple](#), [ST\\_SimplifyPreserveTopology](#), [Topology](#) [ST\\_Simplify](#)

### 8.11.29 ST\_SimplifyPreserveTopology

`ST_SimplifyPreserveTopology` — Returns a "simplified" version of the given geometry using the Douglas-Peucker algorithm. Will avoid creating derived geometries (polygons in particular) that are invalid.

## Synopsis

```
geometry ST_SimplifyPreserveTopology(geometry geomA, float tolerance);
```

## Description

Returns a "simplified" version of the given geometry using the Douglas-Peucker algorithm. Will avoid creating derived geometries (polygons in particular) that are invalid. Will actually do something only with (multi)lines and (multi)polygons but you can safely call it with any kind of geometry. Since simplification occurs on a object-by-object basis you can also feed a GeometryCollection to this function.

Performed by the GEOS module.

### Note

Requires GEOS 3.0.0+

Availability: 1.3.3

## Examples

Same example as `Simplify`, but we see `Preserve Topology` prevents oversimplification. The circle can at most become a square.

```
SELECT ST_Npoints(the_geom) As np_before, ST_NPoints(ST_SimplifyPreserveTopology(the_geom ←
,0.1)) As np01_notbadcircle, ST_NPoints(ST_SimplifyPreserveTopology(the_geom,0.5)) As ←
np05_notquitecircle,
ST_NPoints(ST_SimplifyPreserveTopology(the_geom,1)) As np1_octagon, ST_NPoints(←
ST_SimplifyPreserveTopology(the_geom,10)) As np10_square,
ST_NPoints(ST_SimplifyPreserveTopology(the_geom,100)) As np100_stillsquare
FROM (SELECT ST_Buffer('POINT(1 3)', 10,12) As the_geom) As foo;
```

--result--

np_before	np01_notbadcircle	np05_notquitecircle	np1_octagon	np10_square	np100_stillsquare
49	33	17	9	5	←
	5				

## See Also

[ST\\_Simplify](#)

### 8.11.30 ST\_SimplifyVW

`ST_SimplifyVW` — Returns a "simplified" version of the given geometry using the Visvalingam-Whyatt algorithm

## Synopsis

```
geometry ST_SimplifyVW(geometry geomA, float tolerance);
```

## Description

Returns a "simplified" version of the given geometry using the Visvalingam-Whyatt algorithm. Will actually do something only with (multi)lines and (multi)polygons but you can safely call it with any kind of geometry. Since simplification occurs on a object-by-object basis you can also feed a GeometryCollection to this function.

**Note**

Note that returned geometry might lose its simplicity (see [ST\\_IsSimple](#))

**Note**

Note topology may not be preserved and may result in invalid geometries. Use (see [ST\\_SimplifyPreserveTopology](#)) to preserve topology.

**Note**

This function handles 3D and the third dimension will affect the result.

Availability: 2.2.0

**Examples**

A LineString is simplified with a minimum area threshold of 30.

```
select ST_AsText(ST_SimplifyVW(geom,30)) simplified
FROM (SELECT 'LINESTRING(5 2, 3 8, 6 20, 7 25, 10 10)::geometry geom) As foo;
-result
simplified
-----+-----+
LINESTRING(5 2,7 25,10 10)
```

**See Also**

[ST\\_SetEffectiveArea](#), [ST\\_Simplify](#), [ST\\_SimplifyPreserveTopology](#), Topology [ST\\_Simplify](#)

**8.11.31 ST\_SetEffectiveArea**

**ST\_SetEffectiveArea** — Sets the effective area for each vertex, storing the value in the M ordinate. A simplified geometry can then be generated by filtering on the M ordinate.

**Synopsis**

```
geometry ST_SetEffectiveArea(geometry geomA, float threshold = 0, integer set_area = 1);
```

**Description**

Sets the effective area for each vertex, using the Visvalingam-Whyatt algorithm. The effective area is stored as the M-value of the vertex. If the optional "threshold" parameter is used, a simplified geometry will be returned, containing only vertices with an effective area greater than or equal to the threshold value.

This function can be used for server-side simplification when a threshold is specified. Another option is to use a threshold value of zero. In this case, the full geometry will be returned with effective areas as M-values, which can be used by the client to simplify very quickly.

Will actually do something only with (multi)lines and (multi)polygons but you can safely call it with any kind of geometry. Since simplification occurs on a object-by-object basis you can also feed a GeometryCollection to this function.

**Note**

Note that returned geometry might lose its simplicity (see [ST\\_IsSimple](#))

**Note**

Note topology may not be preserved and may result in invalid geometries. Use (see [ST\\_SimplifyPreserveTopology](#)) to preserve topology.

**Note**

The output geometry will lose all previous information in the M-values

**Note**

This function handles 3D and the third dimension will affect the effective area

Availability: 2.2.0

**Examples**

Calculating the effective area of a LineString. Because we use a threshold value of zero, all vertices in the input geometry are returned.

```
select ST_AsText(ST_SetEffectiveArea(geom)) all_pts, ST_AsText(ST_SetEffectiveArea(geom,30) ↔
) thrshld_30
FROM (SELECT 'LINESTRING(5 2, 3 8, 6 20, 7 25, 10 10)::geometry geom) As foo;
-result
all_pts | thrshld_30
-----+-----+
LINESTRING M (5 2 3.40282346638529e+38,3 8 29,6 20 1.5,7 25 49.5,10 10 3.40282346638529e ↔
+38) | LINESTRING M (5 2 3.40282346638529e+38,7 25 49.5,10 10 3.40282346638529e+38)
```

**See Also**

[ST\\_SimplifyVW](#)

**8.11.32 ST\_Split**

`ST_Split` — Returns a collection of geometries resulting by splitting a geometry.

**Synopsis**

geometry `ST_Split`(geometry input, geometry blade);

## Description

The function supports splitting a line by (multi)point, (multi)line or (multi)polygon boundary, a (multi)polygon by line. The returned geometry is always a collection.

Think of this function as the opposite of `ST_Union`. Theoretically applying `ST_Union` to the elements of the returned collection should always yield the original geometry.

Availability: 2.0.0

Changed: 2.2.0 support for splitting a line by a multiline, a multipoint or (multi)polygon boundary was introduced.

### Note

To improve the robustness of `ST_Split` it may be convenient to `ST_Snap` the input to the blade in advance using a very low tolerance. Otherwise the internally used coordinate grid may cause tolerance problems, where coordinates of input and blade do not fall onto each other and the input is not being split correctly (see [#2192](#)).

### Note

When a (multi)polygon is passed as as the blade, its linear component (the boundary) is used for cutting the input.

## Examples

### Polygon Cut by Line

```
-- this creates a geometry collection consisting of the 2 halves of the polygon
-- this is similar to the example we demonstrated in ST_BuildArea
SELECT ST_Split(circle, line)
FROM (SELECT
 ST_MakeLine(ST_MakePoint(10, 10),ST_MakePoint(190, 190)) As line,
 ST_Buffer(ST_GeomFromText('POINT(100 90)'), 50) As circle) As foo;
```

```
-- result --
GEOMETRYCOLLECTION(POLYGON((150 90,149.039264020162 80.2454838991936,146.193976625564 ←
 70.8658283817455,..), POLYGON(..))

-- To convert to individual polygons, you can use ST_Dump or ST_GeometryN
SELECT ST_AsText((ST_Dump(ST_Split(circle, line))).geom) As wkt
FROM (SELECT
 ST_MakeLine(ST_MakePoint(10, 10),ST_MakePoint(190, 190)) As line,
 ST_Buffer(ST_GeomFromText('POINT(100 90)'), 50) As circle) As foo;

-- result --
wkt

POLYGON((150 90,149.039264020162 80.2454838991936,..))
POLYGON((60.1371179574584 60.1371179574584,58.4265193848728 ←
 62.2214883490198,53.8060233744357 ..))
```

### Multilinestring Cut by point

```
SELECT ST_AsText(ST_Split(mline, pt)) As wktcut
FROM (SELECT
 ST_GeomFromText('MULTILINESTRING((10 10, 190 190), (15 15, 30 30, 100 90))') As mline,
 ST_Point(30,30) As pt) As foo;

wktcut

GEOMETRYCOLLECTION(
 LINestring(10 10,30 30),
 LINestring(30 30,190 190),
 LINestring(15 15,30 30),
 LINestring(30 30,100 90)
)
```

**See Also**

**8.11.33 ST\_SymDifference**

`ST_SymDifference` — Returns a geometry that represents the portions of A and B that do not intersect. It is called a symmetric difference because  $ST\_SymDifference(A,B) = ST\_SymDifference(B,A)$ .

**Synopsis**

```
geometry ST_SymDifference(geometry geomA, geometry geomB);
```

**Description**

Returns a geometry that represents the portions of A and B that do not intersect. It is called a symmetric difference because  $ST\_SymDifference(A,B) = ST\_SymDifference(B,A)$ . One can think of this as  $ST\_Union(geomA,geomB) - ST\_Intersection(A,B)$ .

Performed by the GEOS module

**Note**

Do not call with a `GeometryCollection` as an argument

---

This method implements the [OpenGIS Simple Features Implementation Specification for SQL 1.1](#). s2.1.1.3

This method implements the SQL/MM specification. SQL-MM 3: 5.1.21

This function supports 3d and will not drop the z-index. However it seems to only consider x y when doing the difference and tacks back on the Z-Index

**Examples**

---

```
--Safe for 2d - symmetric difference of 2 line strings
SELECT ST_AsText(
 ST_SymDifference(
 ST_GeomFromText('LINESTRING(50 100, 50 200)'),
 ST_GeomFromText('LINESTRING(50 50, 50 150)')
)
);

st_astext

MULTILINESTRING((50 150,50 200),(50 50,50 100))
```

```
--When used in 3d doesn't quite do the right thing
SELECT ST_AsEWKT(ST_SymDifference(ST_GeomFromEWKT('LINESTRING(1 2 1, 1 4 2)'),
 ST_GeomFromEWKT('LINESTRING(1 1 3, 1 3 4)')));

st_astext

### 8.11.34 ST\_Subdivide

**ST\_Subdivide** — Returns a set of geometry where no geometry in the set has more than the specified number of vertices.

#### Synopsis

setof geometry **ST\_Subdivide**(geometry geom, integer max\_vertices=256);

## Description

Turns a single geometry into a set in which each element has fewer than the maximum allowed number of vertices. Useful for converting excessively large polygons and other objects into small portions that fit within the database page size. Uses the same envelope clipping as `ST_ClipByBox2D` does, recursively subdividing the input geometry until all portions have less than the maximum vertex count. Minimum vertex count allowed is 8 and if you try to specify lower than 8, it will throw an error.

Clipping performed by the GEOS module.

### Note

Requires GEOS 3.5.0+

---

Availability: 2.2.0 requires GEOS  $\geq$  3.5.0.

## Examples

```
-- Create a new subdivided table suitable for joining to the original
CREATE TABLE subdivided_geoms AS
SELECT pkey, ST_Subdivide(geom) AS geom
FROM original_geoms;
```

---

### *Subdivide max 10 vertices*

```
SELECT row_number() OVER() As rn, ST_AsText(geom) As wkt
FROM (SELECT ST_SubDivide('POLYGON((132 10,119 23,85 35,68 29,66 28,49 42,32 56,22 ←
 64,32 110,40 119,36 150,

### 8.11.35 ST\_SwapOrdinates

`ST_SwapOrdinates` — Returns a version of the given geometry with given ordinate values swapped.

#### Synopsis

```
geometry ST_SwapOrdinates(geometry geom, cstring ords);
```

#### Description

Returns a version of the given geometry with given ordinates swapped.

The `ords` parameter is a 2-characters string naming the ordinates to swap. Valid names are: x,y,z and m.

Availability: 2.2.0

This method supports Circular Strings and Curves

This function supports 3d and will not drop the z-index.

This function supports M coordinates.

This function supports Polyhedral surfaces.

This function supports Triangles and Triangulated Irregular Network Surfaces (TIN).

### Example

```
-- Scale M value by 2
SELECT ST_AsText(
 ST_SwapOrdinates(
 ST_Scale(
 ST_SwapOrdinates(g, 'xm'),
 2, 1
),
 'xm')
) FROM (SELECT 'POINT ZM (0 0 0 2):::geometry g) foo;

POINT ZM (0 0 0 4)
```

### See Also

[ST\\_FlipCoordinates](#)

## 8.11.36 ST\_Union

`ST_Union` — Returns a geometry that represents the point set union of the Geometries.

### Synopsis

```
geometry ST_Union(geometry set g1field);
geometry ST_Union(geometry g1, geometry g2);
geometry ST_Union(geometry[] g1_array);
```

### Description

Output type can be a MULTI\*, single geometry, or Geometry Collection. Comes in 2 variants. Variant 1 unions 2 geometries resulting in a new geometry with no intersecting regions. Variant 2 is an aggregate function that takes a set of geometries and unions them into a single `ST_Geometry` resulting in no intersecting regions.

Aggregate version: This function returns a MULTI geometry or NON-MULTI geometry from a set of geometries. The `ST_Union()` function is an "aggregate" function in the terminology of PostgreSQL. That means that it operates on rows of data, in the same way the `SUM()` and `AVG()` functions do and like most aggregates, it also ignores NULL geometries.

Non-Aggregate version: This function returns a geometry being a union of two input geometries. Output type can be a MULTI\*, NON-MULTI or GEOMETRYCOLLECTION. If any are NULL, then NULL is returned.

**Note**

ST\_Collect and ST\_Union are often interchangeable. ST\_Union is in general orders of magnitude slower than ST\_Collect because it tries to dissolve boundaries and reorder geometries to ensure that a constructed Multi\* doesn't have intersecting regions.

Performed by the GEOS module.

NOTE: this function was formerly called GeomUnion(), which was renamed from "Union" because UNION is an SQL reserved word.

Availability: 1.4.0 - ST\_Union was enhanced. ST\_Union(geomarray) was introduced and also faster aggregate collection in PostgreSQL. If you are using GEOS 3.1.0+ ST\_Union will use the faster Cascaded Union algorithm described in <http://blog.cleverelephant.ca/2009/01/must-faster-unions-in-postgis-14.html>

This method implements the [OpenGIS Simple Features Implementation Specification for SQL 1.1. s2.1.1.3](#)

**Note**

Aggregate version is not explicitly defined in OGC SPEC.

This method implements the SQL/MM specification. SQL-MM 3: 5.1.19 the z-index (elevation) when polygons are involved.

**Examples****Aggregate example**

```
SELECT stusps,
 ST_Multi(ST_Union(f.the_geom)) as singlegeom
FROM sometable As f
GROUP BY stusps
```

**Non-Aggregate example**

```
SELECT ST_AsText(ST_Union(ST_GeomFromText('POINT(1 2)'),
 ST_GeomFromText('POINT(-2 3)')))

st_astext

MULTIPOINT(-2 3,1 2)

SELECT ST_AsText(ST_Union(ST_GeomFromText('POINT(1 2)'),
 ST_GeomFromText('POINT(1 2)')));
st_astext

```

**See Also**

[ST\\_Collect](#) [ST\\_UnaryUnion](#)

**8.11.37 ST\_UnaryUnion**

**ST\_UnaryUnion** — Like **ST\_Union**, but working at the geometry component level.

**Synopsis**

```
geometry ST_UnaryUnion(geometry geom);
```

**Description**

Unlike **ST\_Union**, **ST\_UnaryUnion** does dissolve boundaries between components of a multipolygon (invalid) and does perform union between the components of a geometrycollection. Each components of the input geometry is assumed to be valid, so you won't get a valid multipolygon out of a bow-tie polygon (invalid).

You may use this function to node a set of linestrings. You may mix **ST\_UnaryUnion** with **ST\_Collect** to fine-tune how many geometries at once you want to dissolve to be nice on both memory size and CPU time, finding the balance between **ST\_Union** and **ST\_MemUnion**.

This function supports 3d and will not drop the z-index.

Availability: 2.0.0 - requires GEOS  $\geq$  3.3.0.

### 8.11.38 ST\_VoronoiLines

`ST_VoronoiLines` — Returns the boundaries between the cells of the Voronoi diagram constructed from the vertices of a geometry.

#### Synopsis

```
geometry ST_VoronoiLines(g1 geometry , tolerance float8 , extend_to geometry);
```

#### Description

`ST_VoronoiLines` computes a two-dimensional [Voronoi diagram](#) from the vertices of the supplied geometry and returns the boundaries between cells in that diagram as a `MultiLineString`.

Optional parameters:

- `'tolerance'` : The distance within which vertices will be considered equivalent. Robustness of the algorithm can be improved by supplying a nonzero tolerance distance. (default = 0.0)
- `'extend_to'` : If a geometry is supplied as the "extend\_to" parameter, the diagram will be extended to cover the envelope of the "extend\_to" geometry, unless that envelope is smaller than the default envelope. (default = NULL)

Availability: 2.3.0 - requires GEOS  $\geq$  3.5.0.

#### Examples

---

*Voronoi lines with tolerance of 30 units*

```
SELECT ST_VoronoiLines(geom, 30) As geom
FROM (SELECT 'MULTIPOINT (50 30, 60 30, 100 100,10 150, 110 120)>:::geometry As geom) ←
 As g

-- ST_AsText output

### 8.11.39 ST\_VoronoiPolygons

`ST_VoronoiPolygons` — Returns the cells of the Voronoi diagram constructed from the vertices of a geometry.

#### Synopsis

```
geometry ST_VoronoiPolygons(g1 geometry , tolerance float8 , extend_to geometry);
```

#### Description

`ST_VoronoiPolygons` computes a two-dimensional **Voronoi diagram** from the vertices of the supplied geometry. The result is a `GeometryCollection` of `Polygons` that covers an envelope larger than the extent of the input vertices.

Optional parameters:

- `'tolerance'` : The distance within which vertices will be considered equivalent. Robustness of the algorithm can be improved by supplying a nonzero tolerance distance. (default = 0.0)
- `'extend_to'` : If a geometry is supplied as the "extend\_to" parameter, the diagram will be extended to cover the envelope of the "extend\_to" geometry, unless that envelope is smaller than the default envelope. (default = NULL)

Availability: 2.3.0 - requires GEOS >= 3.5.0.

## Examples

## 8.12 Linear Referencing

### 8.12.1 ST\_LineInterpolatePoint

**ST\_LineInterpolatePoint** — Returns a point interpolated along a line. Second argument is a float8 between 0 and 1 representing fraction of total length of linestring the point has to be located.

#### Synopsis

```
geometry ST_LineInterpolatePoint(geometry a_linestring, float8 a_fraction);
```

#### Description

Returns a point interpolated along a line. First argument must be a LINESRING. Second argument is a float8 between 0 and 1 representing fraction of total linestring length the point has to be located.

See [ST\\_LineLocatePoint](#) for computing the line location nearest to a Point.

**Note**

Since release 1.1.1 this function also interpolates M and Z values (when present), while prior releases set them to 0.0.

Availability: 0.8.2, Z and M supported added in 1.1.1

Changed: 2.1.0. Up to 2.0.x this was called ST\_Line\_Interpolate\_Point.

This function supports 3d and will not drop the z-index.

**Examples**

*A linestring with the interpolated point at 20% position (0.20)*

```
--Return point 20% along 2d line
SELECT ST_AsEWKT(ST_LineInterpolatePoint(the_line, 0.20))
 FROM (SELECT ST_GeomFromEWKT('LINESTRING(25 50, 100 125, 150 190)') as the_line) As foo;
 st_asewkt

POINT(51.5974135047432 76.5974135047432)
```

```
--Return point mid-way of 3d line
SELECT ST_AsEWKT(ST_LineInterpolatePoint(the_line, 0.5))
 FROM (SELECT ST_GeomFromEWKT('LINESTRING(1 2 3, 4 5 6, 6 7 8)') as the_line) As foo;

 st_asewkt

POINT(3.5 4.5 5.5)
```

```
--find closest point on a line to a point or other geometry
SELECT ST_AsText(ST_LineInterpolatePoint(foo.the_line, ST_LineLocatePoint(foo.the_line, ←
 ST_GeomFromText('POINT(4 3)'))))
FROM (SELECT ST_GeomFromText('LINESTRING(1 2, 4 5, 6 7)') As the_line) As foo;
 st_astext

POINT(3 4)
```

**See Also**

[ST\\_AsText](#), [ST\\_AsEWKT](#), [ST\\_Length](#), [ST\\_LineLocatePoint](#)

**8.12.2 ST\_LineLocatePoint**

`ST_LineLocatePoint` — Returns a float between 0 and 1 representing the location of the closest point on `LineString` to the given `Point`, as a fraction of total 2d line length.

**Synopsis**

```
float8 ST_LineLocatePoint(geometry a_linestring, geometry a_point);
```

**Description**

Returns a float between 0 and 1 representing the location of the closest point on `LineString` to the given `Point`, as a fraction of total **2d line** length.

You can use the returned location to extract a `Point` ([ST\\_LineInterpolatePoint](#)) or a substring ([ST\\_LineSubstring](#)).

This is useful for approximating numbers of addresses

Availability: 1.1.0

Changed: 2.1.0. Up to 2.0.x this was called `ST_Line_Locate_Point`.

**Examples**

```
--Rough approximation of finding the street number of a point along the street
--Note the whole foo thing is just to generate dummy data that looks
--like house centroids and street
--We use ST_DWithin to exclude
--houses too far away from the street to be considered on the street
SELECT ST_AsText(house_loc) As as_text_house_loc,
 startstreet_num +
 CAST((endstreet_num - startstreet_num)
 * ST_LineLocatePoint(street_line, house_loc) As integer) As street_num
FROM
 (SELECT ST_GeomFromText('LINESTRING(1 2, 3 4)') As street_line,

### 8.12.3 ST\_LineSubstring

`ST_LineSubstring` — Return a linestring being a substring of the input one starting and ending at the given fractions of total 2d length. Second and third arguments are float8 values between 0 and 1.

#### Synopsis

```
geometry ST_LineSubstring(geometry a_linestring, float8 startfraction, float8 endfraction);
```

#### Description

Return a linestring being a substring of the input one starting and ending at the given fractions of total 2d length. Second and third arguments are float8 values between 0 and 1. This only works with LINESTRINGS. To use with contiguous MULTILINESTRINGS use in conjunction with [ST\\_LineMerge](#).

If 'start' and 'end' have the same value this is equivalent to [ST\\_LineInterpolatePoint](#).

See [ST\\_LineLocatePoint](#) for computing the line location nearest to a Point.

#### Note

Since release 1.1.1 this function also interpolates M and Z values (when present), while prior releases set them to unspecified values.

---

Availability: 1.1.0, Z and M supported added in 1.1.1

Changed: 2.1.0. Up to 2.0.x this was called `ST_Line_Substring`.

This function supports 3d and will not drop the z-index.

#### Examples

*A linestring seen with 1/3 midrange overlaid (0.333, 0.666)*

---

```

--Return the approximate 1/3 mid-range part of a linestring
SELECT ST_AsText(ST_Line_SubString(ST_GeomFromText('LINESTRING(25 50, 100 125, 150 190)'), ←
 0.333, 0.666));

 st_astext

LINESTRING(69.2846934853974 94.2846934853974,100 125,111.700356260683 140.210463138888)

--The below example simulates a while loop in
--SQL using PostgreSQL generate_series() to cut all
--linestrings in a table to 100 unit segments
-- of which no segment is longer than 100 units
-- units are measured in the SRID units of measurement
-- It also assumes all geometries are LINESTRING or contiguous MULTILINESTRING
--and no geometry is longer than 100 units*10000
--for better performance you can reduce the 10000
--to match max number of segments you expect

SELECT field1, field2, ST_LineSubstring(the_geom, 100.00*n/length,
CASE
WHEN 100.00*(n+1) < length THEN 100.00*(n+1)/length
ELSE 1
END) As the_geom
FROM
(SELECT sometable.field1, sometable.field2,
ST_LineMerge(sometable.the_geom) AS the_geom,
ST_Length(sometable.the_geom) As length
FROM sometable
) AS t
CROSS JOIN generate_series(0,10000) AS n
WHERE n*100.00/length < 1;

```

**See Also**

[ST\\_Length](#), [ST\\_LineInterpolatePoint](#), [ST\\_LineMerge](#)

**8.12.4 ST\_LocateAlong**

**ST\_LocateAlong** — Return a derived geometry collection value with elements that match the specified measure. Polygonal elements are not supported.

**Synopsis**

```
geometry ST_LocateAlong(geometry geom_with_measure, float8 a_measure, float8 offset);
```

**Description**

Return a derived geometry collection value with elements that match the specified measure. Polygonal elements are not supported.

If an offset is provided, the resultant will be offset to the left or right of the input line by the specified number of units. A positive offset will be to the left, and a negative one to the right.

Semantic is specified by: ISO/IEC CD 13249-3:200x(E) - Text for Continuation CD Editing Meeting

Availability: 1.1.0 by old name `ST_Locate_Alone_Measure`.

Changed: 2.0.0 in prior versions this used to be called `ST_Locate_Along_Measure`. The old name has been deprecated and will be removed in the future but is still available.

#### Note

Use this function only for geometries with an M component

This function supports M coordinates.

## Examples

```
SELECT ST_AsText(the_geom)
 FROM
 (SELECT ST_LocateAlong(
 ST_GeomFromText('MULTILINESTRINGM((1 2 3, 3 4 2, 9 4 3),
(1 2 3, 5 4 5))'),3) As the_geom) As foo;

### 8.12.5 ST\_LocateBetween

`ST_LocateBetween` — Return a derived geometry collection value with elements that match the specified range of measures inclusively. Polygonal elements are not supported.

#### Synopsis

geometry **ST\_LocateBetween**(geometry geomA, float8 measure\_start, float8 measure\_end, float8 offset);

## Description

Return a derived geometry collection value with elements that match the specified range of measures inclusively. Polygonal elements are not supported.

Semantic is specified by: ISO/IEC CD 13249-3:200x(E) - Text for Continuation CD Editing Meeting

Availability: 1.1.0 by old name `ST_Locate_Between_Measures`.

Changed: 2.0.0 - in prior versions this used to be called `ST_Locate_Between_Measures`. The old name has been deprecated and will be removed in the future but is still available for backward compatibility.

This function supports M coordinates.

## Examples

```
SELECT ST_AsText(the_geom)
FROM
 (SELECT ST_LocateBetween(
 ST_GeomFromText('MULTILINESTRING M ((1 2 3, 3 4 2, 9 4 3),
 (1 2 3, 5 4 5))'),1.5, 3) As the_geom) As foo;

 st_asewkt

### 8.12.6 ST\_LocateBetweenElevations

`ST_LocateBetweenElevations` — Return a derived geometry (collection) value with elements that intersect the specified range of elevations inclusively. Only 3D, 4D `LINESTRING`s and `MULTILINESTRING`s are supported.

## Synopsis

geometry `ST_LocateBetweenElevations`(geometry geom\_mline, float8 elevation\_start, float8 elevation\_end);

**Description**

Return a derived geometry (collection) value with elements that intersect the specified range of elevations inclusively. Only 3D, 3DM LINESTRINGS and MULTILINESTRINGS are supported.

Availability: 1.4.0

This function supports 3d and will not drop the z-index.

**Examples**

```
SELECT ST_AsEWKT(ST_LocateBetweenElevations(
 ST_GeomFromEWKT('LINESTRING(1 2 3, 4 5 6)'),2,4)) As ewelev;

MULTILINESTRING((1 2 3,2 3 4))

[ST\\_Dump](#)

**8.12.7 ST\_InterpolatePoint**

**ST\_InterpolatePoint** — Return the value of the measure dimension of a geometry at the point closed to the provided point.

**Synopsis**

```
float8 ST_InterpolatePoint(geometry line, geometry point);
```

**Description**

Return the value of the measure dimension of a geometry at the point closed to the provided point.

Availability: 2.0.0

This function supports 3d and will not drop the z-index.

**Examples**

```
SELECT ST_InterpolatePoint('LINESTRING M (0 0 0, 10 0 20)', 'POINT(5 5)');
st_interpolatepoint

10
```

**See Also**

[ST\\_AddMeasure](#), [ST\\_LocateAlong](#), [ST\\_LocateBetween](#)

**8.12.8 ST\_AddMeasure**

**ST\_AddMeasure** — Return a derived geometry with measure elements linearly interpolated between the start and end points.

**Synopsis**

geometry **ST\_AddMeasure**(geometry geom\_mline, float8 measure\_start, float8 measure\_end);

**Description**

Return a derived geometry with measure elements linearly interpolated between the start and end points. If the geometry has no measure dimension, one is added. If the geometry has a measure dimension, it is over-written with new values. Only **LINESTRINGS** and **MULTILINESTRINGS** are supported.

Availability: 1.5.0

This function supports 3d and will not drop the z-index.

**Examples**

```
SELECT ST_AsText(ST_AddMeasure(
ST_GeomFromEWKT('LINESTRING(1 0, 2 0, 4 0)'),1,4)) As ewelev;
 ewelev

LINESTRINGM(1 0 1,2 0 2,4 0 4)

SELECT ST_AsText(ST_AddMeasure(
ST_GeomFromEWKT('LINESTRING(1 0 4, 2 0 4, 4 0 4)'),10,40)) As ewelev;
 ewelev

LINESTRING(1 0 4 10,2 0 4 20,4 0 4 40)

SELECT ST_AsText(ST_AddMeasure(
ST_GeomFromEWKT('LINESTRINGM(1 0 4, 2 0 4, 4 0 4)'),10,40)) As ewelev;
 ewelev

LINESTRINGM(1 0 10,2 0 20,4 0 40)

SELECT ST_AsText(ST_AddMeasure(
ST_GeomFromEWKT('MULTILINESTRINGM((1 0 4, 2 0 4, 4 0 4),(1 0 4, 2 0 4, 4 0 4)'),10,70)) As ←
 ewelev;
 ewelev

MULTILINESTRINGM((1 0 10,2 0 20,4 0 40),(1 0 40,2 0 50,4 0 70))
```

## 8.13 Temporal Support

### 8.13.1 ST\_IsValidTrajectory

`ST_IsValidTrajectory` — Returns `true` if the geometry is a valid trajectory.

#### Synopsis

```
boolean ST_IsValidTrajectory(geometry line);
```

#### Description

Tell if a geometry encodes a valid trajectory. Valid trajectories are encoded as `LINestring` with `M` value growing from each vertex to the next.

Valid trajectories are expected as input to some spatio-temporal queries like [ST\\_ClosestPointOfApproach](#)

Availability: 2.2.0

This function supports 3d and will not drop the z-index.

#### Examples

```
-- A valid trajectory
SELECT ST_IsValidTrajectory(ST_MakeLine(
 ST_MakePointM(0,0,1),
 ST_MakePointM(0,1,2))
);
t

-- An invalid trajectory
SELECT ST_IsValidTrajectory(ST_MakeLine(ST_MakePointM(0,0,1), ST_MakePointM(0,1,0)));
NOTICE: Measure of vertex 1 (0) not bigger than measure of vertex 0 (1)
st_isvalidtrajectory

f
```

#### See Also

[ST\\_ClosestPointOfApproach](#)

### 8.13.2 ST\_ClosestPointOfApproach

`ST_ClosestPointOfApproach` — Returns the measure at which points interpolated along two lines are closest.

#### Synopsis

```
float8 ST_ClosestPointOfApproach(geometry track1, geometry track2);
```

**Description**

Returns the smallest measure at which point interpolated along the given lines are at the smallest distance. Inputs must be valid trajectories as checked by [ST\\_IsValidTrajectory](#). Null is returned if the trajectories do not overlap on the M range.

See [ST\\_LocateAlong](#) for getting the actual points at the given measure.

Availability: 2.2.0

This function supports 3d and will not drop the z-index.

**Examples**

```
-- Return the time in which two objects moving between 10:00 and 11:00
-- are closest to each other and their distance at that point
WITH inp AS (SELECT
 ST_AddMeasure('LINESTRING Z (0 0 0, 10 0 5)::geometry,
 extract(epoch from '2015-05-26 10:00'::timestampz),
 extract(epoch from '2015-05-26 11:00'::timestampz)
) a,
 ST_AddMeasure('LINESTRING Z (0 2 10, 12 1 2)::geometry,
 extract(epoch from '2015-05-26 10:00'::timestampz),
 extract(epoch from '2015-05-26 11:00'::timestampz)
) b
), cpa AS (
 SELECT ST_ClosestPointOfApproach(a,b) m FROM inp
), points AS (

```

**See Also**

[ST\\_IsValidTrajectory](#), [ST\\_DistanceCPA](#), [ST\\_LocateAlong](#), [ST\\_AddMeasure](#)

**8.13.3 ST\_DistanceCPA**

**ST\_DistanceCPA** — Returns the distance between closest points of approach in two trajectories.

**Synopsis**

```
float8 ST_DistanceCPA(geometry track1, geometry track2);
```

**Description**

Returns the minimum distance two moving objects have ever been each-other. Inputs must be valid trajectories as checked by [ST\\_IsValidTrajectory](#). Null is returned if the trajectories do not overlap on the M range.

Availability: 2.2.0

This function supports 3d and will not drop the z-index.

### Examples

```
-- Return the minimum distance of two objects moving between 10:00 and 11:00
WITH inp AS (SELECT
 ST_AddMeasure('LINESTRING Z (0 0 0, 10 0 5)::geometry,

## 8.13.4 ST\_CPAWithin

`ST_CPAWithin` — Returns true if the trajectories' closest points of approach are within the specified distance.

### Synopsis

```
float8 ST_CPAWithin(geometry track1, geometry track2, float8 maxdist);
```

### Description

Checks whether two moving objects have ever been within the specified max distance.

Inputs must be valid trajectories as checked by [ST\\_IsValidTrajectory](#). False is returned if the trajectories do not overlap on the M range.

Availability: 2.2.0

This function supports 3d and will not drop the z-index.

### Examples

```
WITH inp AS (SELECT
 ST_AddMeasure('LINESTRING Z (0 0 0, 10 0 5)::geometry,
 extract(epoch from '2015-05-26 10:00'::timestampz),
 extract(epoch from '2015-05-26 11:00'::timestampz)
) a,
 ST_AddMeasure('LINESTRING Z (0 2 10, 12 1 2)::geometry,

## 8.14 Long Transactions Support

This module and associated pl/pgsql functions have been implemented to provide long locking support required by [Web Feature Service](#) specification.

**Note**

Users must use [serializable transaction level](#) otherwise locking mechanism would break.

### 8.14.1 AddAuth

AddAuth — Add an authorization token to be used in current transaction.

**Synopsis**

boolean **AddAuth**(text auth\_token);

**Description**

Add an authorization token to be used in current transaction.

Creates/adds to a temp table called temp\_lock\_have\_table the current transaction identifier and authorization token key.

Availability: 1.1.3

**Examples**

```

SELECT LockRow('towns', '353', 'priscilla');
BEGIN TRANSACTION;
 SELECT AddAuth('joey');
 UPDATE towns SET the_geom = ST_Translate(the_geom,2,2) WHERE gid = 353;
COMMIT;

---Error---
ERROR: UPDATE where "gid" = '353' requires authorization 'priscilla'

```

**See Also**[LockRow](#)**8.14.2 CheckAuth**

CheckAuth — Creates trigger on a table to prevent/allow updates and deletes of rows based on authorization token.

**Synopsis**

```
integer CheckAuth(text a_schema_name, text a_table_name, text a_key_column_name);
integer CheckAuth(text a_table_name, text a_key_column_name);
```

**Description**

Creates trigger on a table to prevent/allow updates and deletes of rows based on authorization token. Identify rows using <rowid\_col> column.

If a\_schema\_name is not passed in, then searches for table in current schema.

**Note**

If an authorization trigger already exists on this table function errors.  
If Transaction support is not enabled, function throws an exception.

Availability: 1.1.3

**Examples**

```
SELECT CheckAuth('public', 'towns', 'gid');
result

0
```

**See Also**[EnableLongTransactions](#)**8.14.3 DisableLongTransactions**

DisableLongTransactions — Disable long transaction support. This function removes the long transaction support metadata tables, and drops all triggers attached to lock-checked tables.

**Synopsis**

```
text DisableLongTransactions();
```

### Description

Disable long transaction support. This function removes the long transaction support metadata tables, and drops all triggers attached to lock-checked tables.

Drops meta table called `authorization_table` and a view called `authorized_tables` and all triggers called `check_authtrigger`

Availability: 1.1.3

### Examples

```
SELECT DisableLongTransactions();
--result--
Long transactions support disabled
```

### See Also

[EnableLongTransactions](#)

## 8.14.4 EnableLongTransactions

`EnableLongTransactions` — Enable long transaction support. This function creates the required metadata tables, needs to be called once before using the other functions in this section. Calling it twice is harmless.

### Synopsis

```
text EnableLongTransactions();
```

### Description

Enable long transaction support. This function creates the required metadata tables, needs to be called once before using the other functions in this section. Calling it twice is harmless.

Creates a meta table called `authorization_table` and a view called `authorized_tables`

Availability: 1.1.3

### Examples

```
SELECT EnableLongTransactions();
--result--
Long transactions support enabled
```

### See Also

[DisableLongTransactions](#)

## 8.14.5 LockRow

`LockRow` — Set lock/authorization for specific row in table

**Synopsis**

```
integer LockRow(text a_schema_name, text a_table_name, text a_row_key, text an_auth_token, timestamp expire_dt);
integer LockRow(text a_table_name, text a_row_key, text an_auth_token, timestamp expire_dt);
integer LockRow(text a_table_name, text a_row_key, text an_auth_token);
```

**Description**

Set lock/authorization for specific row in table <authid> is a text value, <expires> is a timestamp defaulting to now()+1hour. Returns 1 if lock has been assigned, 0 otherwise (already locked by other auth)

Availability: 1.1.3

**Examples**

```
SELECT LockRow('public', 'towns', '2', 'joey');
LockRow

1

--Joey has already locked the record and Priscilla is out of luck
SELECT LockRow('public', 'towns', '2', 'priscilla');
LockRow

0
```

**See Also**

[UnlockRows](#)

**8.14.6 UnlockRows**

UnlockRows — Remove all locks held by specified authorization id. Returns the number of locks released.

**Synopsis**

```
integer UnlockRows(text auth_token);
```

**Description**

Remove all locks held by specified authorization id. Returns the number of locks released.

Availability: 1.1.3

**Examples**

```
SELECT LockRow('towns', '353', 'priscilla');
SELECT LockRow('towns', '2', 'priscilla');
SELECT UnLockRows('priscilla');
UnLockRows

2
```

**See Also**[LockRow](#)

## 8.15 Miscellaneous Functions

### 8.15.1 ST\_Accum

ST\_Accum — Aggregate. Constructs an array of geometries.

**Synopsis**

```
geometry[] ST_Accum(geometry set geomfield);
```

**Description**

Aggregate. Constructs an array of geometries.

Enhanced: 2.0.0 support for Polyhedral surfaces, Triangles and TIN was introduced.

This function supports 3d and will not drop the z-index.

This method supports Circular Strings and Curves

This function supports Polyhedral surfaces.

This function supports Triangles and Triangulated Irregular Network Surfaces (TIN).

**Examples**

```
SELECT (ST_Accum(the_geom)) As all_em, ST_AsText((ST_Accum(the_geom))[1]) As grabone,
(ST_Accum(the_geom))[2:4] as grab_rest
FROM (SELECT ST_MakePoint(a*CAST(random()*10 As integer), a*CAST(random()*10 As
integer), a*CAST(random()*10 As integer)) As the_geom
FROM generate_series(1,4) a) As foo;
```

```
all_em|grabone | grab_rest
```

```

```

**See Also**[ST\\_Collect](#)

## 8.15.2 Box2D

Box2D — Returns a BOX2D representing the maximum extents of the geometry.

### Synopsis

```
box2d Box2D(geometry geomA);
```

### Description

Returns a BOX2D representing the maximum extents of the geometry.

Enhanced: 2.0.0 support for Polyhedral surfaces, Triangles and TIN was introduced.

This method supports Circular Strings and Curves

This function supports Polyhedral surfaces.

This function supports Triangles and Triangulated Irregular Network Surfaces (TIN).

### Examples

```
SELECT Box2D(ST_GeomFromText('LINESTRING(1 2, 3 4, 5 6)'));
 box2d

BOX(1 2,5 6)

SELECT Box2D(ST_GeomFromText('CIRCULARSTRING(220268 150415,220227 150505,220227 150406)') ←
);

## 8.15.3 Box3D

Box3D — Returns a BOX3D representing the maximum extents of the geometry.

### Synopsis

```
box3d Box3D(geometry geomA);
```

## Description

Returns a BOX3D representing the maximum extents of the geometry.

Enhanced: 2.0.0 support for Polyhedral surfaces, Triangles and TIN was introduced.

This method supports Circular Strings and Curves

This function supports Polyhedral surfaces.

This function supports Triangles and Triangulated Irregular Network Surfaces (TIN).

This function supports 3d and will not drop the z-index.

## Examples

```
SELECT Box3D(ST_GeomFromEWKT('LINESTRING(1 2 3, 3 4 5, 5 6 5)'));
Box3d

BOX3D(1 2 3,5 6 5)

SELECT Box3D(ST_GeomFromEWKT('CIRCULARSTRING(220268 150415 1,220227 150505 1,220227 150406 1)'));
Box3d

## 8.15.4 ST\_EstimatedExtent

**ST\_EstimatedExtent** — Return the 'estimated' extent of the given spatial table. The estimated is taken from the geometry column's statistics. The current schema will be used if not specified.

### Synopsis

```
box2d ST_EstimatedExtent(text schema_name, text table_name, text geocolumn_name, boolean parent_ony);
box2d ST_EstimatedExtent(text schema_name, text table_name, text geocolumn_name);
box2d ST_EstimatedExtent(text table_name, text geocolumn_name);
```

### Description

Return the 'estimated' extent of the given spatial table. The estimated is taken from the geometry column's statistics. The current schema will be used if not specified. The default behavior is to also use statistics collected from children tables (tables with INHERITS) if available. If 'parent\_ony' is set to TRUE, only statistics for the given table are used and children tables are ignored.

For PostgreSQL >= 8.0.0 statistics are gathered by VACUUM ANALYZE and resulting extent will be about 95% of the real one.

**Note**

In absence of statistics (empty table or no ANALYZE called) this function returns NULL. Prior to version 1.5.4 an exception was thrown instead.

For PostgreSQL<8.0.0 statistics are gathered by `update_geometry_stats()` and resulting extent will be exact.

Availability: 1.0.0

Changed: 2.1.0. Up to 2.0.x this was called `ST_Estimated_Extent`.

This method supports Circular Strings and Curves

**Examples**

```
SELECT ST_EstimatedExtent('ny', 'edges', 'the_geom');
--result--
BOX(-8877653 4912316,-8010225.5 5589284)

SELECT ST_EstimatedExtent('feature_poly', 'the_geom');
--result--
BOX(-124.659652709961 24.6830825805664,-67.7798080444336 49.0012092590332)
```

**See Also**

[ST\\_Extent](#)

**8.15.5 ST\_Expand**

`ST_Expand` — Returns bounding box expanded in all directions from the bounding box of the input geometry. Uses double-precision

**Synopsis**

```
geometry ST_Expand(geometry geom, float units_to_expand);
geometry ST_Expand(geometry geom, float dx, float dy, float dz=0, float dm=0);
box2d ST_Expand(box2d box, float units_to_expand);
box2d ST_Expand(box2d box, float dx, float dy);
box3d ST_Expand(box3d box, float units_to_expand);
box3d ST_Expand(box3d box, float dx, float dy, float dz=0);
```

**Description**

This function returns a bounding box expanded from the bounding box of the input, either by specifying a single distance with which the box should be expanded in all directions, or by specifying an expansion distance for each direction. Uses double-precision. Can be very useful for distance queries, or to add a bounding box filter to a query to take advantage of a spatial index.

In addition to the geometry version of `ST_Expand`, which is the most commonly used, variants are provided that accept and produce internal BOX2D and BOX3D data types.

`ST_Expand` is similar in concept to `ST_Buffer`, except while buffer expands the geometry in all directions, `ST_Expand` expands the bounding box an x,y,z unit amount.

Units are in the units of the spatial reference system in use denoted by the SRID.

**Note**

Pre 1.3, `ST_Expand` was used in conjunction with `distance` to do indexable queries. Something of the form `the_geom && ST_Expand('POINT(10 20)', 10) AND ST_Distance(the_geom, 'POINT(10 20)') < 10` Post 1.2, this was replaced with the easier `ST_DWithin` construct.

**Note**

Availability: 1.5.0 behavior changed to output double precision instead of float4 coordinates.  
 Enhanced: 2.0.0 support for Polyhedral surfaces, Triangles and TIN was introduced.  
 Enhanced: 2.3.0 support was added to expand a box by different amounts in different dimensions.

This function supports Polyhedral surfaces.

This function supports Triangles and Triangulated Irregular Network Surfaces (TIN).

**Examples****Note**

Examples below use US National Atlas Equal Area (SRID=2163) which is a meter projection

```
--10 meter expanded box around bbox of a linestring
SELECT CAST(ST_Expand(ST_GeomFromText('LINESTRING(2312980 110676,2312923 110701,2312892 110714)', 2163),10) As box2d);
 st_expand

BOX(2312882 110666,2312990 110724)

--10 meter expanded 3d box of a 3d box
SELECT ST_Expand(CAST('BOX3D(778783 2951741 1,794875 2970042.61545891 10)' As box3d),10)
 st_expand

BOX3D(778773 2951731 -9,794885 2970052.61545891 20)

--10 meter geometry astext rep of a expand box around a point geometry
SELECT ST_AsEWKT(ST_Expand(ST_GeomFromEWKT('SRID=2163;POINT(2312980 110676)'),10));
 st_asewkt

SRID=2163;POLYGON((2312970 110666,2312970 110686,2312990 110686,2312990 110666,2312970 110666))
```

**8.15.6 ST\_Extent**

`ST_Extent` — an aggregate function that returns the bounding box that bounds rows of geometries.

## Synopsis

box2d **ST\_Extent**(geometry set geomfield);

## Description

ST\_Extent returns a bounding box that encloses a set of geometries. The ST\_Extent function is an "aggregate" function in the terminology of SQL. That means that it operates on lists of data, in the same way the SUM() and AVG() functions do.

Since it returns a bounding box, the spatial Units are in the units of the spatial reference system in use denoted by the SRID

ST\_Extent is similar in concept to Oracle Spatial/Locator's SDO\_AGGR\_MBR

### Note

Since ST\_Extent returns a bounding box, the SRID meta-data is lost. Use ST\_SetSRID to force it back into a geometry with SRID meta data. The coordinates are in the units of the spatial ref of the original geometries.

### Note

ST\_Extent will return boxes with only an x and y component even with (x,y,z) coordinate geometries. To maintain x,y,z use ST\_3DExtent instead.

### Note

Availability: 1.4.0

Enhanced: 2.0.0 support for Polyhedral surfaces, Triangles and TIN was introduced.

This function supports Polyhedral surfaces.

This function supports Triangles and Triangulated Irregular Network Surfaces (TIN).

## Examples

### Note

Examples below use Massachusetts State Plane ft (SRID=2249)

```
SELECT ST_Extent(the_geom) as bextent FROM sometable;
 st_bextent
```

```

BOX(739651.875 2908247.25,794875.8125 2970042.75)
```

```
--Return extent of each category of geometries
```

```
SELECT ST_Extent(the_geom) as bextent
FROM sometable
GROUP BY category ORDER BY category;
```

```

 bextent | name
-----+-----
BOX(778783.5625 2951741.25,794875.8125 2970042.75) | A
BOX(751315.8125 2919164.75,765202.6875 2935417.25) | B
BOX(739651.875 2917394.75,756688.375 2935866) | C

--Force back into a geometry
-- and render the extended text representation of that geometry
SELECT ST_SetSRID(ST_Extent(the_geom),2249) as bextent FROM sometable;

 bextent

SRID=2249;POLYGON((739651.875 2908247.25,739651.875 2970042.75,794875.8125 2970042.75,
794875.8125 2908247.25,739651.875 2908247.25))

```

**See Also**

[ST\\_AsEWKT](#), [ST\\_3DExtent](#), [ST\\_SetSRID](#), [ST\\_SRID](#)

**8.15.7 ST\_3DExtent**

`ST_3DExtent` — an aggregate function that returns the box3D bounding box that bounds rows of geometries.

**Synopsis**

box3d `ST_3DExtent`(geometry set geomfield);

**Description**

`ST_3DExtent` returns a box3d (includes Z coordinate) bounding box that encloses a set of geometries. The `ST_3DExtent` function is an "aggregate" function in the terminology of SQL. That means that it operates on lists of data, in the same way the `SUM()` and `AVG()` functions do.

Since it returns a bounding box, the spatial Units are in the units of the spatial reference system in use denoted by the SRID

**Note**

Since `ST_3DExtent` returns a bounding box, the SRID meta-data is lost. Use `ST_SetSRID` to force it back into a geometry with SRID meta data. The coordinates are in the units of the spatial ref of the original geometries.

Enhanced: 2.0.0 support for Polyhedral surfaces, Triangles and TIN was introduced.

Changed: 2.0.0 In prior versions this used to be called `ST_Extent3D`

This function supports 3d and will not drop the z-index.

This method supports Circular Strings and Curves

This function supports Polyhedral surfaces.

This function supports Triangles and Triangulated Irregular Network Surfaces (TIN).

## Examples

```

SELECT ST_3DExtent(foo.the_geom) As b3extent
FROM (SELECT ST_MakePoint(x,y,z) As the_geom
 FROM generate_series(1,3) As x
 CROSS JOIN generate_series(1,2) As y
 CROSS JOIN generate_series(0,2) As Z) As foo;
 b3extent

BOX3D(1 1 0,3 2 2)

--Get the extent of various elevated circular strings
SELECT ST_3DExtent(foo.the_geom) As b3extent
FROM (SELECT ST_Translate(ST_Force_3DZ(ST_LineToCurve(ST_Buffer(ST_MakePoint(x,y),1))),0,0, ←
 z) As the_geom
 FROM generate_series(1,3) As x
 CROSS JOIN generate_series(1,2) As y
 CROSS JOIN generate_series(0,2) As Z) As foo;

 b3extent

BOX3D(1 0 0,4 2 2)

```

## 8.15.8 Find\_SRID

**Find\_SRID** — The syntax is `find_srid(a_db_schema, a_table, a_column)` and the function returns the integer SRID of the specified column by searching through the `GEOMETRY_COLUMNS` table.

### Synopsis

integer **Find\_SRID**(varchar a\_schema\_name, varchar a\_table\_name, varchar a\_geomfield\_name);

### Description

The syntax is `find_srid(<db/schema>, <table>, <column>)` and the function returns the integer SRID of the specified column by searching through the `GEOMETRY_COLUMNS` table. If the geometry column has not been properly added with the `AddGeometryColumns()` function, this function will not work either.

### Examples

```

SELECT Find_SRID('public', 'tiger_us_state_2007', 'the_geom_4269');
find_srid

4269

```

## See Also

[ST\\_SRID](#)

### 8.15.9 ST\_MemSize

ST\_MemSize — Returns the amount of space (in bytes) the geometry takes.

#### Synopsis

```
integer ST_MemSize(geometry geomA);
```

#### Description

Returns the amount of space (in bytes) the geometry takes.

This is a nice compliment to PostgreSQL built in functions `pg_column_size`, `pg_size_pretty`, `pg_relation_size`, `pg_total_relation_size`.

#### Note

`pg_relation_size` which gives the byte size of a table may return byte size lower than `ST_MemSize`. This is because `pg_relation_size` does not add toasted table contribution and large geometries are stored in TOAST tables.

`pg_total_relation_size` - includes, the table, the toasted tables, and the indexes.

`pg_column_size` returns how much space a geometry would take in a column considering compression, so may be lower than `ST_MemSize`

This function supports 3d and will not drop the z-index.

This method supports Circular Strings and Curves

This function supports Polyhedral surfaces.

This function supports Triangles and Triangulated Irregular Network Surfaces (TIN).

Changed: 2.2.0 name changed to `ST_MemSize` to follow naming convention. In prior versions this function was called `ST_Mem_Size`, old name deprecated though still available.

#### Examples

```
--Return how much byte space Boston takes up in our Mass data set
SELECT pg_size_pretty(SUM(ST_MemSize(the_geom))) as totgeomsum,
pg_size_pretty(SUM(CASE WHEN town = 'BOSTON' THEN ST_MemSize(the_geom) ELSE 0 END)) As bossum,
CAST(SUM(CASE WHEN town = 'BOSTON' THEN ST_MemSize(the_geom) ELSE 0 END)*1.00 /
SUM(ST_MemSize(the_geom))*100 As numeric(10,2)) As perbos
FROM towns;
```

```
totgeomsum bossum perbos

1522 kB 30 kB 1.99
```

```
SELECT ST_MemSize(ST_GeomFromText('CIRCULARSTRING(220268 150415,220227 150505,220227
150406)'));

```

```
73
```

```
--What percentage of our table is taken up by just the geometry
```

```

SELECT pg_total_relation_size('public.neighborhoods') As fulltable_size, sum(ST_MemSize(←
 the_geom)) As geomsizesize,
sum(ST_MemSize(the_geom))*1.00/pg_total_relation_size('public.neighborhoods')*100 As ←
 pergeom
FROM neighborhoods;
fulltable_size geomsizesize pergeom

262144 96238 36.71188354492187500000

```

**See Also****8.15.10 ST\_PointInsideCircle**

**ST\_PointInsideCircle** — Is the point geometry insert circle defined by center\_x, center\_y, radius

**Synopsis**

boolean **ST\_PointInsideCircle**(geometry a\_point, float center\_x, float center\_y, float radius);

**Description**

The syntax for this functions is **ST\_PointInsideCircle**(<geometry>,<circle\_center\_x>,<circle\_center\_y>,<radius>). Returns the true if the geometry is a point and is inside the circle. Returns false otherwise.

**Note**

This only works for points as the name suggests

Availability: 1.2

Changed: 2.2.0 In prior versions this used to be called `ST_Point_Inside_Circle`

**Examples**

```

SELECT ST_PointInsideCircle(ST_Point(1,2), 0.5, 2, 3);
st_pointinsidecircle

t

```

**See Also**

[ST\\_DWithin](#)

**8.16 Exceptional Functions**

These functions are rarely used functions that should only be used if your data is corrupted in someway. They are used for troubleshooting corruption and also fixing things that should under normal circumstances, never happen.

### 8.16.1 PostGIS\_AddBBox

PostGIS\_AddBBox — Add bounding box to the geometry.

#### Synopsis

```
geometry PostGIS_AddBBox(geometry geomA);
```

#### Description

Add bounding box to the geometry. This would make bounding box based queries faster, but will increase the size of the geometry.

#### Note

Bounding boxes are automatically added to geometries so in general this is not needed unless the generated bounding box somehow becomes corrupted or you have an old install that is lacking bounding boxes. Then you need to drop the old and readd.

This method supports Circular Strings and Curves

#### Examples

```
UPDATE sometable
SET the_geom = PostGIS_AddBBox(the_geom)
WHERE PostGIS_HasBBox(the_geom) = false;
```

#### See Also

[PostGIS\\_DropBBox](#), [PostGIS\\_HasBBox](#)

### 8.16.2 PostGIS\_DropBBox

PostGIS\_DropBBox — Drop the bounding box cache from the geometry.

#### Synopsis

```
geometry PostGIS_DropBBox(geometry geomA);
```

#### Description

Drop the bounding box cache from the geometry. This reduces geometry size, but makes bounding-box based queries slower. It is also used to drop a corrupt bounding box. A tale-tell sign of a corrupt cached bounding box is when your ST\_Intersects and other relation queries leave out geometries that rightfully should return true.

#### Note

Bounding boxes are automatically added to geometries and improve speed of queries so in general this is not needed unless the generated bounding box somehow becomes corrupted or you have an old install that is lacking bounding boxes. Then you need to drop the old and readd. This kind of corruption has been observed in 8.3-8.3.6 series whereby cached bboxes were not always recalculated when a geometry changed and upgrading to a newer version without a dump reload will not correct already corrupted boxes. So one can manually correct using below and readd the bbox or do a dump reload.

This method supports Circular Strings and Curves

### Examples

```
--This example drops bounding boxes where the cached box is not correct
--The force to ST_AsBinary before applying Box2D forces a recalculation of the box, ←
 and Box2D applied to the table geometry always
-- returns the cached bounding box.
UPDATE sometable
SET the_geom = PostGIS_DropBBox(the_geom)
WHERE Not (Box2D(ST_AsBinary(the_geom)) = Box2D(the_geom));

UPDATE sometable
SET the_geom = PostGIS_AddBBox(the_geom)
WHERE Not PostGIS_HasBBOX(the_geom);
```

### See Also

[PostGIS\\_AddBBox](#), [PostGIS\\_HasBBox](#), [Box2D](#)

### 8.16.3 PostGIS\_HasBBox

`PostGIS_HasBBox` — Returns TRUE if the bbox of this geometry is cached, FALSE otherwise.

### Synopsis

boolean `PostGIS_HasBBox`(geometry geomA);

### Description

Returns TRUE if the bbox of this geometry is cached, FALSE otherwise. Use [PostGIS\\_AddBBox](#) and [PostGIS\\_DropBBox](#) to control caching.

This method supports Circular Strings and Curves

### Examples

```
SELECT the_geom
FROM sometable WHERE PostGIS_HasBBox(the_geom) = false;
```

### See Also

[PostGIS\\_AddBBox](#), [PostGIS\\_DropBBox](#)

## 9.1 Raster Support Data types

### 9.1.1 geomval

`geomval` — A spatial datatype with two fields - `geom` (holding a geometry object) and `val` (holding a double precision pixel value from a raster band).

#### Description

`geomval` is a compound data type consisting of a geometry object referenced by the `.geom` field and `val`, a double precision value that represents the pixel value at a particular geometric location in a raster band. It is used by the `ST_DumpAsPolygon` and Raster intersection family of functions as an output type to explode a raster band into geometry polygons.

#### See Also

Section [14.6](#)

### 9.1.2 addbandarg

`addbandarg` — A composite type used as input into the `ST_AddBand` function defining the attributes and initial value of the new band.

#### Description

A composite type used as input into the `ST_AddBand` function defining the attributes and initial value of the new band.

***index* integer** 1-based value indicating the position where the new band will be added amongst the raster's bands. If NULL, the new band will be added at the end of the raster's bands.

***pixeltype* text** Pixel type of the new band. One of defined pixel types as described in [ST\\_BandPixelType](#).

***initialvalue* double precision** Initial value that all pixels of new band will be set to.

***nodataval* double precision** NODATA value of the new band. If NULL, the new band will not have a NODATA value assigned.

#### See Also

[ST\\_AddBand](#)

### 9.1.3 rastbandarg

`rastbandarg` — A composite type for use when needing to express a raster and a band index of that raster.

#### Description

A composite type for use when needing to express a raster and a band index of that raster.

***rast* raster** The raster in question/

***nband* integer** 1-based value indicating the band of raster

**See Also**[ST\\_MapAlgebra](#)**9.1.4 raster**

raster — raster spatial data type.

**Description**

raster is a spatial data type used to represent raster data such as those imported from jpegs, tiffs, pngs, digital elevation models. Each raster has 1 or more bands each having a set of pixel values. Rasters can be georeferenced.

**Note**

Requires PostGIS be compiled with GDAL support. Currently rasters can be implicitly converted to geometry type, but the conversion returns the [ST\\_ConvexHull](#) of the raster. This auto casting may be removed in the near future so don't rely on it.

**Casting Behavior**

This section lists the automatic as well as explicit casts allowed for this data type

Cast To	Behavior
geometry	automatic

**See Also**

Chapter [9](#)

**9.1.5 reclassarg**

reclassarg — A composite type used as input into the ST\_Reclass function defining the behavior of reclassification.

**Description**

A composite type used as input into the ST\_Reclass function defining the behavior of reclassification.

**nband integer** The band number of band to reclassify.

**reclassexpr text** range expression consisting of comma delimited range:map\_range mappings. : to define mapping that defines how to map old band values to new band values. ( means >, ) means less than, ] < or equal, [ means > or equal

1. [a-b] = a <= x <= b
2. (a-b] = a < x <= b
3. [a-b) = a <= x < b
4. (a-b) = a < x < b

( notation is optional so a-b means the same as (a-b)

**pixeltype text** One of defined pixel types as described in [ST\\_BandPixelType](#)

**nodataval double precision** Value to treat as no data. For image outputs that support transparency, these will be blank.

**Example: Reclassify band 2 as an 8BUI where 255 is nodata value**

```
SELECT ROW(2, '0-100:1-10, 101-500:11-150, 501 - 10000: 151-254', '8BUI', 255)::reclassarg;
```

**Example: Reclassify band 1 as an 1BB and no nodata value defined**

```
SELECT ROW(1, '0-100]:0, (100-255:1', '1BB', NULL)::reclassarg;
```

**See Also**

[ST\\_Reclass](#)

### 9.1.6 summarystats

summarystats — A composite type returned by the [ST\\_SummaryStats](#) and [ST\\_SummaryStatsAgg](#) functions.

**Description**

A composite type returned by the [ST\\_SummaryStats](#) and [ST\\_SummaryStatsAgg](#) functions.

**count integer** Number of pixels counted for the summary statistics.

**sum double precision** Sum of all counted pixel values.

**mean double precision** Arithmetic mean of all counted pixel values.

**stdev double precision** Standard deviation of all counted pixel values.

**min double precision** Minimum value of counted pixel values.

**max double precision** Maximum value of counted pixel values.

**See Also**

[ST\\_SummaryStats](#), [ST\\_SummaryStatsAgg](#)

### 9.1.7 unionarg

unionarg — A composite type used as input into the [ST\\_Union](#) function defining the bands to be processed and behavior of the UNION operation.

**Description**

A composite type used as input into the [ST\\_Union](#) function defining the bands to be processed and behavior of the UNION operation.

**nband integer** 1-based value indicating the band of each input raster to be processed.

**uniontype text** Type of UNION operation. One of defined types as described in [ST\\_Union](#).

**See Also**[ST\\_Union](#)

## 9.2 Raster Management

### 9.2.1 AddRasterConstraints

**AddRasterConstraints** — Adds raster constraints to a loaded raster table for a specific column that constrains spatial ref, scaling, blocksize, alignment, bands, band type and a flag to denote if raster column is regularly blocked. The table must be loaded with data for the constraints to be inferred. Returns true if the constraint setting was accomplished and if issues a notice.

**Synopsis**

```
boolean AddRasterConstraints(name rasttable, name rastcolumn, boolean srid, boolean scale_x, boolean scale_y, boolean
blocksize_x, boolean blocksize_y, boolean same_alignment, boolean regular_blocking, boolean num_bands=true, boolean
pixel_types=true, boolean nodata_values=true, boolean out_db=true, boolean extent=true);
boolean AddRasterConstraints(name rasttable, name rastcolumn, text[] VARIADIC constraints);
boolean AddRasterConstraints(name rastschema, name rasttable, name rastcolumn, text[] VARIADIC constraints);
boolean AddRasterConstraints(name rastschema, name rasttable, name rastcolumn, boolean srid=true, boolean scale_x=true,
boolean scale_y=true, boolean blocksize_x=true, boolean blocksize_y=true, boolean same_alignment=true, boolean regular_blocking=true,
boolean num_bands=true, boolean pixel_types=true, boolean nodata_values=true, boolean out_db=true, boolean extent=true);
```

**Description**

Generates constraints on a raster column that are used to display information in the `raster_columns` raster catalog. The `rastschema` is the name of the table schema the table resides in. The `srid` must be an integer value reference to an entry in the `SPATIAL_REF_SYS` table.

`raster2pgsql` loader uses this function to register raster tables

Valid constraint names to pass in: refer to Section 5.2.1 for more details.

- `blocksize` sets both X and Y blocksize
- `blocksize_x` sets X tile (width in pixels of each tile)
- `blocksize_y` sets Y tile (height in pixels of each tile)
- `extent` computes extent of whole table and applies constraint all rasters must be within that extent
- `num_bands` number of bands
- `pixel_types` reads array of pixel types for each band ensure all band n have same pixel type
- `regular_blocking` sets spatially unique (no two rasters can be spatially the same) and coverage tile (raster is aligned to a coverage) constraints
- `same_alignment` ensures they all have same alignment meaning any two tiles you compare will return true for. Refer to [ST\\_SameAlignment](#)
- `srid` ensures all have same srid
- More -- any listed as inputs into the above functions

**Note**

This function infers the constraints from the data already present in the table. As such for it to work, you must create the raster column first and then load it with data.

**Note**

If you need to load more data in your tables after you have already applied constraints, you may want to run the `DropRasterConstraints` if the extent of your data has changed.

Availability: 2.0.0

**Examples: Apply all possible constraints on column based on data**

```
CREATE TABLE myrasters(rid SERIAL primary key, rast raster);
INSERT INTO myrasters(rast)
SELECT ST_AddBand(ST_MakeEmptyRaster(1000, 1000, 0.3, -0.3, 2, 2, 0, 0,4326), 1, '8BSI':: ↵
 text, -129, NULL);

SELECT AddRasterConstraints('myrasters'::name, 'rast'::name);

-- verify if registered correctly in the raster_columns view --
SELECT srid, scale_x, scale_y, blocksize_x, blocksize_y, num_bands, pixel_types, ↵
 nodata_values
FROM raster_columns
WHERE r_table_name = 'myrasters';
```

srid	scale_x	scale_y	blocksize_x	blocksize_y	num_bands	pixel_types	nodata_values
4326	2	2	1000	1000	1	{8BSI}	{0}

**Examples: Apply single constraint**

```
CREATE TABLE public.myrasters2(rid SERIAL primary key, rast raster);
INSERT INTO myrasters2(rast)
SELECT ST_AddBand(ST_MakeEmptyRaster(1000, 1000, 0.3, -0.3, 2, 2, 0, 0,4326), 1, '8BSI':: ↵
 text, -129, NULL);

## 9.2.2 DropRasterConstraints

**DropRasterConstraints** — Drops PostGIS raster constraints that refer to a raster table column. Useful if you need to reload data or update your raster column data.

### Synopsis

```
boolean DropRasterConstraints(name rasttable, name rastcolumn, boolean srid, boolean scale_x, boolean scale_y, boolean
blocksize_x, boolean blocksize_y, boolean same_alignment, boolean regular_blocking, boolean num_bands=true, boolean pixel_types=true,
boolean no data_values=true, boolean out_db=true, boolean extent=true);
boolean DropRasterConstraints(name rastschema, name rasttable, name rastcolumn, boolean srid=true, boolean scale_x=true,
boolean scale_y=true, boolean blocksize_x=true, boolean blocksize_y=true, boolean same_alignment=true, boolean regular_blocking=false,
boolean num_bands=true, boolean pixel_types=true, boolean no data_values=true, boolean out_db=true, boolean extent=true);
boolean DropRasterConstraints(name rastschema, name rasttable, name rastcolumn, text[] constraints);
```

### Description

Drops PostGIS raster constraints that refer to a raster table column that were added by [AddRasterConstraints](#). Useful if you need to load more data or update your raster column data. You do not need to do this if you want to get rid of a raster table or a raster column.

To drop a raster table use the standard

```
DROP TABLE mytable
```

To drop just a raster column and leave the rest of the table, use standard SQL

```
ALTER TABLE mytable DROP COLUMN rast
```

the table will disappear from the `raster_columns` catalog if the column or table is dropped. However if only the constraints are dropped, the raster column will still be listed in the `raster_columns` catalog, but there will be no other information about it aside from the column name and table.

Availability: 2.0.0

### Examples

```
SELECT DropRasterConstraints ('myrasters', 'rast');
```

```
----RESULT output ---
```

```
t
```

```
-- verify change in raster_columns --
```

```
SELECT srid, scale_x, scale_y, blocksize_x, blocksize_y, num_bands, pixel_types, ←
 no data_values
FROM raster_columns
WHERE r_table_name = 'myrasters';
```

```
 srid | scale_x | scale_y | blocksize_x | blocksize_y | num_bands | pixel_types | ←
-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+----- ←
```

```
 0 | | | | | | | | | | |
```

### 9.2.3 AddOverviewConstraints

AddOverviewConstraints — Tag a raster column as being an overview of another.

#### Synopsis

boolean **AddOverviewConstraints**(name ovschema, name ovtable, name ovcolumn, name refschema, name reftable, name refcolumn, int ovfactor);

boolean **AddOverviewConstraints**(name ovtable, name ovcolumn, name reftable, name refcolumn, int ovfactor);

#### Description

Adds constraints on a raster column that are used to display information in the `raster_overviews` raster catalog.

The `ovfactor` parameter represents the scale multiplier in the overview column: higher overview factors have lower resolution.

When the `ovschema` and `refschema` parameters are omitted, the first table found scanning the `search_path` will be used.

Availability: 2.0.0

#### Examples

```
CREATE TABLE res1 AS SELECT
ST_AddBand(
 ST_MakeEmptyRaster(1000, 1000, 0, 0, 2),
 1, '8BSI'::text, -129, NULL
) r1;

CREATE TABLE res2 AS SELECT
ST_AddBand(
 ST_MakeEmptyRaster(500, 500, 0, 0, 4),
 1, '8BSI'::text, -129, NULL
) r2;

SELECT AddOverviewConstraints('res2', 'r2', 'res1', 'r1', 2);

-- verify if registered correctly in the raster_overviews view --
SELECT o_table_name ot, o_raster_column oc,
 r_table_name rt, r_raster_column rc,
 overview_factor f
FROM raster_overviews WHERE o_table_name = 'res2';
 ot | oc | rt | rc | f
-----+-----+-----+-----+----
 res2 | r2 | res1 | r1 | 2
(1 row)
```

### 9.2.4 DropOverviewConstraints

DropOverviewConstraints — Untag a raster column from being an overview of another.

## Synopsis

boolean **DropOverviewConstraints**(name ovschema, name ovtable, name ovcolumn);  
boolean **DropOverviewConstraints**(name ovtable, name ovcolumn);

## Description

Remove from a raster column the constraints used to show it as being an overview of another in the `raster_overviews` raster catalog.

When the `ovschema` parameter is omitted, the first table found scanning the `search_path` will be used.

Availability: 2.0.0

## 9.2.5 PostGIS\_GDAL\_Version

`PostGIS_GDAL_Version` — Reports the version of the GDAL library in use by PostGIS.

## Synopsis

text **PostGIS\_GDAL\_Version**();

## Description

Reports the version of the GDAL library in use by PostGIS. Will also check and report if GDAL can find its data files.

## Examples

```
SELECT PostGIS_GDAL_Version();
 postgis_gdal_version

GDAL 1.11dev, released 2013/04/13
```

## See Also

**9.2.8 ST\_GDALDrivers**

ST\_GDALDrivers — Returns a list of raster formats supported by your lib gdal. These are the formats you can output your raster using ST\_AsGDALRaster.

**Synopsis**

setof record **ST\_GDALDrivers**(integer OUT idx, text OUT short\_name, text OUT long\_name, text OUT create\_options);

---

## Description

Returns a list of raster formats `short_name`, `long_name` and creator options of each format supported by your lib gdal. Use the `short_name` as input in the `format` parameter of `ST_AsGDALRaster`. Options vary depending on what drivers your libgdal was compiled with. `create_options` returns an xml formatted set of `CreationOptionList/Option` consisting of name and optional type, description and set of `VALUE` for each creator option for the specific driver.

Changed: 2.0.6, 2.1.3 - by default no drivers are enabled, unless GUC or Environment variable `gdal_enabled_drivers` is set.

Availability: 2.0.0 - requires GDAL >= 1.6.0.

## Examples: List of Drivers

```
SET postgis.gdal_enabled_drivers = 'ENABLE_ALL';
SELECT short_name, long_name
FROM st_gdaldrivers()
ORDER BY short_name;
```

short_name	long_name
AAIGrid	Arc/Info ASCII Grid
ARG	Azavea Raster Grid format
DTED	DTED Elevation Raster
EHdr	ESRI .hdr Labelled
FIT	FIT Image
GIF	Graphics Interchange Format (.gif)
GPKG	GeoPackage
GS7BG	Golden Software 7 Binary Grid (.grd)
GSAG	Golden Software ASCII Grid (.grd)
GSBG	Golden Software Binary Grid (.grd)
GTiff	GeoTIFF
HF2	HF2/HFZ heightfield raster
HFA	Erdas Imagine Images (.img)
ILWIS	ILWIS Raster Map
INGR	Intergraph Raster
JPEG	JPEG JFIF
KMLSUPEROVERLAY	Kml Super Overlay
LCP	FARSITE v.4 Landscape File (.lcp)

**9.2.9 UpdateRasterSRID**

UpdateRasterSRID — Change the SRID of all rasters in the user-specified column and table.

**Synopsis**

```
raster UpdateRasterSRID(name schema_name, name table_name, name column_name, integer new_srid);
raster UpdateRasterSRID(name table_name, name column_name, integer new_srid);
```

**Description**

Change the SRID of all rasters in the user-specified column and table. The function will drop all appropriate column constraints (extent, alignment and SRID) before changing the SRID of the specified column's rasters.

**Note**

The data (band pixel values) of the rasters are not touched by this function. Only the raster's metadata is changed.

Availability: 2.1.0

**See Also**

[UpdateGeometrySRID](#)

## 9.2.10 ST\_CreateOverview

`ST_CreateOverview` — Create an reduced resolution version of a given raster coverage.

### Synopsis

```
regclass ST_CreateOverview(regclass tab, name col, int factor, text algo='NearestNeighbor');
```

### Description

Create an overview table with resampled tiles from the source table. Output tiles will have the same size of input tiles and cover the same spatial extent with a lower resolution (pixel size will be  $1/\text{factor}$  of the original in both directions).

The overview table will be made available in the `raster_oversiews` catalog and will have raster constraints enforced.

Algorithm options are: 'NearestNeighbor', 'Bilinear', 'Cubic', 'CubicSpline', and 'Lanczos'. Refer to: [GDAL Warp resampling methods](#) for more details.

Availability: 2.2.0

### See Also

[ST\\_Retile](#), [AddOverviewConstraints](#), [AddRasterConstraints](#), [Section 5.2.2](#)

## 9.3 Raster Constructors

### 9.3.1 ST\_AddBand

`ST_AddBand` — Returns a raster with the new band(s) of given type added with given initial value in the given index location. If no index is specified, the band is added to the end.

### Synopsis

- (1) raster **ST\_AddBand**(raster rast, addbandarg[] addbandargset);
- (2) raster **ST\_AddBand**(raster rast, integer index, text pixelttype, double precision initialvalue=0, double precision nodataval=NULL);
- (3) raster **ST\_AddBand**(raster rast, text pixelttype, double precision initialvalue=0, double precision nodataval=NULL);
- (4) raster **ST\_AddBand**(raster torast, raster fromrast, integer fromband=1, integer torastindex=at\_end);
- (5) raster **ST\_AddBand**(raster torast, raster[] fromrasts, integer fromband=1, integer torastindex=at\_end);
- (6) raster **ST\_AddBand**(raster rast, integer index, text outdbfile, integer[] outdbindex, double precision nodataval=NULL);
- (7) raster **ST\_AddBand**(raster rast, text outdbfile, integer[] outdbindex, integer index=at\_end, double precision nodataval=NULL);

### Description

Returns a raster with a new band added in given position (index), of given type, of given initial value, and of given nodata value. If no index is specified, the band is added to the end. If no `fromband` is specified, band 1 is assumed. Pixel type is a string representation of one of the pixel types specified in [ST\\_BandPixelType](#). If an existing index is specified all subsequent bands  $\geq$  that index are incremented by 1. If an initial value greater than the max of the pixel type is specified, then the initial value is set to the highest value allowed by the pixel type.

For the variant that takes an array of `addbandarg` (Variant 1), a specific `addbandarg`'s index value is relative to the raster at the time when the band described by that `addbandarg` is being added to the raster. See the [Multiple New Bands](#) example below.

For the variant that takes an array of rasters (Variant 5), if `torast` is NULL then the `fromband` band of each raster in the array is accumulated into a new raster.

For the variants that take `outdbfile` (Variants 6 and 7), the value must include the full path to the raster file. The file must also be accessible to the postgres server process.

Enhanced: 2.1.0 support for `addbandarg` added.

Enhanced: 2.1.0 support for new out-db bands added.

### Examples: Single New Band

```
-- Add another band of type 8 bit unsigned integer with pixels initialized to 200
UPDATE dummy_rast
 SET rast = ST_AddBand(rast,'8BUI'::text,200)
WHERE rid = 1;
```

```
-- Create an empty raster 100x100 units, with upper left right at 0, add 2 bands (band 1 ←
 is 0/1 boolean bit switch, band2 allows values 0-15)
-- uses addbandargs
INSERT INTO dummy_rast(rid,rast)
 VALUES(10, ST_AddBand(ST_MakeEmptyRaster(100, 100, 0, 0, 1, -1, 0, 0, 0),
 ARRAY[
 ROW(1, '1BB'::text, 0, NULL),
 ROW(2, '4BUI'::text, 0, NULL)
]::addbandarg[]
)
);
```

```
-- output meta data of raster bands to verify all is right --
SELECT (bmd).*
```

```
FROM (SELECT ST_BandMetaData(rast,generate_series(1,2)) As bmd
 FROM dummy_rast WHERE rid = 10) AS foo;
```

```
--result --
pixeltype | nodatavalue | isoutdb | path
-----+-----+-----+-----
1BB | | f |
4BUI | | f |
```

```
-- output meta data of raster -
SELECT (rmd).width, (rmd).height, (rmd).numbands
FROM (SELECT ST_MetaData(rast) As rmd
 FROM dummy_rast WHERE rid = 10) AS foo;
```

```
-- result --
upperleftx | upperlefty | width | height | scalex | scaley | skewx | skewy | srid | ←
numbands
-----+-----+-----+-----+-----+-----+-----+-----+-----+-----
0 | 0 | 100 | 100 | 1 | -1 | 0 | 0 | 0 | ←
2
```

### Examples: Multiple New Bands

```
SELECT
 *
FROM ST_BandMetadata(
 ST_AddBand(
 ST_MakeEmptyRaster(10, 10, 0, 0, 1, -1, 0, 0, 0),
 ARRAY[
 ROW(NULL, '8BUI', 255, 0),
 ROW(NULL, '16BUI', 1, 2),
```

```

 ROW(2, '32BUI', 100, 12),
 ROW(2, '32BF', 3.14, -1)
]::addbandarg[]
),
ARRAY[]::integer[]
);

```

bandnum	pixeltype	nodatavalue	isoutdb	path
1	8BUI	0	f	
2	32BF	-1	f	
3	32BUI	12	f	
4	16BUI	2	f	

```

-- Aggregate the 1st band of a table of like rasters into a single raster
-- with as many bands as there are test_types and as many rows (new rasters) as there are ←
mice
-- NOTE: The ORDER BY test_type is only supported in PostgreSQL 9.0+
-- for 8.4 and below it usually works to order your data in a subselect (but not guaranteed ←
)
-- The resulting raster will have a band for each test_type alphabetical by test_type
-- For mouse lovers: No mice were harmed in this exercise
SELECT
 mouse,
 ST_AddBand(NULL, array_agg(rast ORDER BY test_type), 1) As rast
FROM mice_studies
GROUP BY mouse;

```

### Examples: New Out-db band

```

SELECT
 *
FROM ST_BandMetadata(
 ST_AddBand(
 ST_MakeEmptyRaster(10, 10, 0, 0, 1, -1, 0, 0, 0),
 '/home/raster/mytestraster.tif'::text, NULL::int[]
),
 ARRAY[]::integer[]
);

```

bandnum	pixeltype	nodatavalue	isoutdb	path
1	8BUI		t	/home/raster/mytestraster.tif
2	8BUI		t	/home/raster/mytestraster.tif
3	8BUI		t	/home/raster/mytestraster.tif

raster ST_AsRaster(geometry geom, double precision scalex, double precision scaley, double precision gridx=NULL, double precision gridy=NULL, text[] pixeltype=ARRAY['8BUI'], double precision[] value=ARRAY[1], double precision[] nodataval=ARRAY[0], double precision skewx=0, double precision skewy=0, boolean touched=false);
raster ST_AsRaster(geometry geom, double precision scalex, double precision scaley, text pixeltype, double precision value=1, double precision nodataval=0, double precision upperleftx=NULL, double precision upperlefty=NULL, double precision skewx=0, double precision skewy=0, boolean touched=false);
raster ST_AsRaster(geometry geom, double precision scalex, double precision scaley, text[] pixeltype, double precision[] value=ARRAY[1], double precision[] nodataval=ARRAY[0], double precision upperleftx=NULL, double precision upperlefty=NULL, double precision skewx=0, double precision skewy=0, boolean touched=false);
raster ST_AsRaster(geometry geom, integer width, integer height, double precision gridx, double precision gridy, text pixeltype, double precision value=1, double precision nodataval=0, double precision skewx=0, double precision skewy=0, boolean touched=false);
raster ST_AsRaster(geometry geom, integer width, integer height, double precision gridx=NULL, double precision gridy=NULL, text[] pixeltype=ARRAY['8BUI'], double precision[] value=ARRAY[1], double precision[] nodataval=ARRAY[0], double precision skewx=0, double precision skewy=0, boolean touched=false);
raster ST_AsRaster(geometry geom, integer width, integer height, text pixeltype, double precision value=1, double precision nodataval=0, double precision upperleftx=NULL, double precision upperlefty=NULL, double precision skewx=0, double precision skewy=0, boolean touched=false);
raster ST_AsRaster(geometry geom, integer width, integer height, text[] pixeltype, double precision[] value=ARRAY[1], double precision[] nodataval=ARRAY[0], double precision upperleftx=NULL, double precision upperlefty=NULL, double precision skewx=0, double precision skewy=0, boolean touched=false);
```

## Description

Converts a PostGIS geometry to a PostGIS raster. The many variants offers three groups of possibilities for setting the alignment and pixelsize of the resulting raster.

The first group, composed of the two first variants, produce a raster having the same alignment (*scalex*, *scaley*, *gridx* and *gridy*), pixel type and nodata value as the provided reference raster. You generally pass this reference raster by joining the table containing the geometry with the table containing the reference raster.

The second group, composed of four variants, let you set the dimensions of the raster by providing the parameters of a pixel size (*scalex* & *scaley* and *skewx* & *skewy*). The width & height of the resulting raster will be adjusted to fit the extent of the geometry. In most cases, you must cast integer *scalex* & *scaley* arguments to double precision so that PostgreSQL choose the right variant.

The third group, composed of four variants, let you fix the dimensions of the raster by providing the dimensions of the raster (*width* & *height*). The parameters of the pixel size (*scalex* & *scaley* and *skewx* & *skewy*) of the resulting raster will be adjusted to fit the extent of the geometry.

The two first variants of each of those two last groups let you specify the alignment with an arbitrary corner of the alignment grid (*gridx* & *gridy*) and the two last variants takes the upper left corner (*upperleftx* & *upperlefty*).

Each group of variant allows producing a one band raster or a multiple bands raster. To produce a multiple bands raster, you must provide an array of pixel types (*pixeltype*[]), an array of initial values (*value*) and an array of nodata values (*nodataval*). If not provided *pixeltype* defaults to 8BUI, *value* to 1 and *nodataval* to 0.

The output raster will be in the same spatial reference as the source geometry. The only exception is for variants with a reference raster. In this case the resulting raster will get the same SRID as the reference raster.

The optional `touched` parameter defaults to `false` and maps to the GDAL `ALL_TOUCHED` rasterization option, which determines if pixels touched by lines or polygons will be burned. Not just those on the line render path, or whose center point is within the polygon.

This is particularly useful for rendering `jpgs` and `pngs` of geometries directly from the database when using in combination with `ST_AsPNG` and other `ST_AsGDALRaster` family of functions.

Availability: 2.0.0 - requires GDAL  $\geq$  1.6.0.

#### Note

Not yet capable of rendering complex geometry types such as curves, TINS, and PolyhedralSurfaces, but should be able too once GDAL can.

### Examples: Output geometries as PNG files

*black circle*

```
-- this will output a black circle taking up 150 x 150 pixels --
SELECT ST_AsPNG(ST_AsRaster(ST_Buffer(ST_Point(1,5),10),150, 150));
```

*example from buffer rendered with just PostGIS*

```
-- the bands map to RGB bands - the value (118,154,118) - teal --
SELECT ST_AsPNG(
 ST_AsRaster(
 ST_Buffer(
 ST_GeomFromText('LINESTRING(50 50,150 150,150 50)'), 10,'join=bevel'),
 200,200,ARRAY['8BUI', '8BUI', '8BUI'], ARRAY[118,154,118], ARRAY[0,0,0]));
```

### 9.3.3 ST\_Band

**ST\_Band** — Returns one or more bands of an existing raster as a new raster. Useful for building new rasters from existing rasters.

#### Synopsis

```
raster ST_Band(raster rast, integer[] nbands = ARRAY[1]);
raster ST_Band(raster rast, integer nband);
raster ST_Band(raster rast, text nbands, character delimiter=,);
```

#### Description

Returns one or more bands of an existing raster as a new raster. Useful for building new rasters from existing rasters or export of only selected bands of a raster or rearranging the order of bands in a raster. If no band is specified, band 1 is assumed. Used as a helper function in various functions such as for deleting a band.

#### Warning

For the `nbands` as text variant of function, the default delimiter is `,` which means you can ask for `'1,2,3'` and if you wanted to use a different delimiter you would do `ST_Band(rast, '1@2@3', '@')`. For asking for multiple bands, we strongly suggest you use the array form of this function e.g. `ST_Band(rast, '{1,2,3}'::int[])`; since the `text` list of bands form may be removed in future versions of PostGIS.

Availability: 2.0.0

#### Examples

```
-- Make 2 new rasters: 1 containing band 1 of dummy, second containing band 2 of dummy and ←
 then reclassified as a 2BUI
SELECT ST_NumBands(rast1) As numb1, ST_BandPixelType(rast1) As pix1,
 ST_NumBands(rast2) As numb2, ST_BandPixelType(rast2) As pix2
FROM (
 SELECT ST_Band(rast) As rast1, ST_Reclass(ST_Band(rast,3), '100-200):1, [200-254:2', '2 ←
 BUI') As rast2
 FROM dummy_rast
 WHERE rid = 2) As foo;
```

```
numb1 | pix1 | numb2 | pix2
-----+-----+-----+-----
 1 | 8BUI | 1 | 2BUI
```

```
-- Return bands 2 and 3. Using array cast syntax
SELECT ST_NumBands(ST_Band(rast, '{2,3}'::int[])) As num_bands
FROM dummy_rast WHERE rid=2;
```

```
num_bands

2
```

```
-- Return bands 2 and 3. Use array to define bands
SELECT ST_NumBands(ST_Band(rast, ARRAY[2,3])) As num_bands
FROM dummy_rast
WHERE rid=2;
```

```
--Make a new raster with 2nd band of original and 1st band repeated twice,
and another with just the third band
SELECT rast, ST_Band(rast, ARRAY[2,1,1]) As dupe_band,
 ST_Band(rast, 3) As sing_band
FROM samples.than_chunked
WHERE rid=35;
```

#### See Also

[ST\\_AddBand](#), [ST\\_NumBands](#), [ST\\_Reclass](#), Chapter 9

### 9.3.4 ST\_MakeEmptyRaster

**ST\_MakeEmptyRaster** — Returns an empty raster (having no bands) of given dimensions (width & height), upperleft X and Y, pixel size and rotation (scalex, scaley, skewx & skewy) and reference system (srid). If a raster is passed in, returns a new raster with the same size, alignment and SRID. If srid is left out, the spatial ref is set to unknown (0).

#### Synopsis

```
raster ST_MakeEmptyRaster(raster rast);
raster ST_MakeEmptyRaster(integer width, integer height, float8 upperleftx, float8 upperlefty, float8 scalex, float8 scaley,
float8 skewx, float8 skewy, integer srid=unknown);
raster ST_MakeEmptyRaster(integer width, integer height, float8 upperleftx, float8 upperlefty, float8 pixelsize);
```

#### Description

Returns an empty raster (having no band) of given dimensions (width & height) and georeferenced in spatial (or world) coordinates with upper left X (upperleftx), upper left Y (upperlefty), pixel size and rotation (scalex, scaley, skewx & skewy) and reference system (srid).

The last version use a single parameter to specify the pixel size (pixelsize). scalex is set to this argument and scaley is set to the negative value of this argument. skewx and skewy are set to 0.

If an existing raster is passed in, it returns a new raster with the same meta data settings (without the bands).

If no srid is specified it defaults to 0. After you create an empty raster you probably want to add bands to it and maybe edit it. Refer to [ST\\_AddBand](#) to define bands and [ST\\_SetValue](#) to set initial pixel values.

## Examples

```

INSERT INTO dummy_rast(rid,rast)
VALUES(3, ST_MakeEmptyRaster(100, 100, 0.0005, 0.0005, 1, 1, 0, 0, 4326));

--use an existing raster as template for new raster
INSERT INTO dummy_rast(rid,rast)
SELECT 4, ST_MakeEmptyRaster(rast)
FROM dummy_rast WHERE rid = 3;

-- output meta data of rasters we just added
SELECT rid, (md).*
FROM (SELECT rid, ST_MetaData(rast) As md
 FROM dummy_rast
 WHERE rid IN(3,4)) As foo;

-- output --
rid | upperleftx | upperlefty | width | height | scalex | scaley | skewx | skewy | srid | ←
-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+
3 | 0.0005 | 0.0005 | 100 | 100 | 1 | 1 | 0 | 0 | 4326 | ←
4 | 0.0005 | 0.0005 | 100 | 100 | 1 | 1 | 0 | 0 | 4326 | ←

```

## 9.3.5 ST\_Tile

**ST\_Tile** — Returns a set of rasters resulting from the split of the input raster based upon the desired dimensions of the output rasters.

### Synopsis

```

setof raster ST_Tile(raster rast, int[] nband, integer width, integer height, boolean padwithnodata=FALSE, double precision nodataval=NULL);
setof raster ST_Tile(raster rast, integer nband, integer width, integer height, boolean padwithnodata=FALSE, double precision nodataval=NULL);
setof raster ST_Tile(raster rast, integer width, integer height, boolean padwithnodata=FALSE, double precision nodataval=NULL);

```

### Description

Returns a set of rasters resulting from the split of the input raster based upon the desired dimensions of the output rasters.

If `padwithnodata = FALSE`, edge tiles on the right and bottom sides of the raster may have different dimensions than the rest of the tiles. If `padwithnodata = TRUE`, all tiles will have the same dimensions with the possibility that edge tiles being padded with NODATA values. If raster band(s) do not have NODATA value(s) specified, one can be specified by setting `nodataval`.

#### Note

If a specified band of the input raster is out-of-db, the corresponding band in the output rasters will also be out-of-db.

Availability: 2.1.0

## Examples

```
WITH foo AS (
 SELECT ST_AddBand(ST_AddBand(ST_MakeEmptyRaster(3, 3, 0, 0, 1, -1, 0, 0, 0), 1, '8BUI', ←
 1, 0), 2, '8BUI', 10, 0) AS rast UNION ALL
 SELECT ST_AddBand(ST_AddBand(ST_MakeEmptyRaster(3, 3, 3, 0, 1, -1, 0, 0, 0), 1, '8BUI', ←
 2, 0), 2, '8BUI', 20, 0) AS rast UNION ALL

### 9.3.6 ST\_Retile

`ST_Retile` — Return a set of configured tiles from an arbitrarily tiled raster coverage.

#### Synopsis

SETOF raster `ST_Retile`(regclass tab, name col, geometry ext, float8 sfx, float8 sfy, int tw, int th, text algo='NearestNeighbor');

#### Description

Return a set of tiles having the specified scale (`sfx`, `sfy`) and max size (`tw`, `th`) and covering the specified extent (`ext`) with data coming from the specified raster coverage (`tab`, `col`).

Algorithm options are: 'NearestNeighbor', 'Bilinear', 'Cubic', 'CubicSpline', and 'Lanczos'. Refer to: [GDAL Warp resampling methods](#) for more details.

Availability: 2.2.0

**See Also**[ST\\_CreateOverview](#)**9.3.7 ST\_FromGDALRaster**

`ST_FromGDALRaster` — Returns a raster from a supported GDAL raster file.

**Synopsis**

```
raster ST_FromGDALRaster(bytea gdaldata, integer srid=NULL);
```

**Description**

Returns a raster from a supported GDAL raster file. `gdaldata` is of type `bytea` and should be the contents of the GDAL raster file.

If `srid` is `NULL`, the function will try to automatically assign the SRID from the GDAL raster. If `srid` is provided, the value provided will override any automatically assigned SRID.

Availability: 2.1.0

**Examples**

```
WITH foo AS (
 SELECT ST_AsPNG(ST_AddBand(ST_AddBand(ST_AddBand(ST_MakeEmptyRaster(2, 2, 0, 0, 0.1, ←
 -0.1, 0, 0, 4326), 1, '8BUI', 1, 0), 2, '8BUI', 2, 0), 3, '8BUI', 3, 0)) AS png
),
bar AS (
 SELECT 1 AS rid, ST_FromGDALRaster(png) AS rast FROM foo
 UNION ALL
 SELECT 2 AS rid, ST_FromGDALRaster(png, 3310) AS rast FROM foo
)
SELECT
 rid,
 ST_Metadata(rast) AS metadata,
 ST_SummaryStats(rast, 1) AS stats1,
 ST_SummaryStats(rast, 2) AS stats2,
 ST_SummaryStats(rast, 3) AS stats3
FROM bar
ORDER BY rid;
```

rid	metadata	stats1	stats2	stats3
1	(0,0,2,2,1,-1,0,0,0,3)	(4,4,1,0,1,1)	(4,8,2,0,2,2)	(4,12,3,0,3,3)
2	(0,0,2,2,1,-1,0,0,3310,3)	(4,4,1,0,1,1)	(4,8,2,0,2,2)	(4,12,3,0,3,3)

(2 rows)

**See Also**[ST\\_AsGDALRaster](#)

## 9.4 Raster Accessors

### 9.4.1 ST\_GeoReference

`ST_GeoReference` — Returns the georeference meta data in GDAL or ESRI format as commonly seen in a world file. Default is GDAL.

#### Synopsis

```
text ST_GeoReference(raster rast, text format=GDAL);
```

#### Description

Returns the georeference meta data including carriage return in GDAL or ESRI format as commonly seen in a [world file](#). Default is GDAL if no type specified. type is string 'GDAL' or 'ESRI'.

Difference between format representations is as follows:

GDAL:

```
scalex
skewy
skewx
scaley
upperleftx
upperlefty
```

ESRI:

```
scalex
skewy
skewx
scaley
upperleftx + scalex*0.5
upperlefty + scaley*0.5
```

#### Examples

```
SELECT ST_GeoReference(rast, 'ESRI') As esri_ref, ST_GeoReference(rast, 'GDAL') As gdal_ref
FROM dummy_rast WHERE rid=1;
```

esri_ref	gdal_ref
2.0000000000	2.0000000000
0.0000000000	0.0000000000
0.0000000000	0.0000000000
3.0000000000	3.0000000000
1.5000000000	0.5000000000
2.0000000000	0.5000000000

#### See Also

[ST\\_SetGeoReference](#), [ST\\_ScaleX](#), [ST\\_ScaleY](#)

## 9.4.2 ST\_Height

`ST_Height` — Returns the height of the raster in pixels.

### Synopsis

integer **ST\_Height**(raster rast);

### Description

Returns the height of the raster.

### Examples

```
SELECT rid, ST_Height(rast) As rastheight
FROM dummy_rast;
```

rid	rastheight
1	20
2	5

### See Also

[ST\\_Width](#)

## 9.4.3 ST\_IsEmpty

`ST_IsEmpty` — Returns true if the raster is empty (width = 0 and height = 0). Otherwise, returns false.

### Synopsis

boolean **ST\_IsEmpty**(raster rast);

### Description

Returns true if the raster is empty (width = 0 and height = 0). Otherwise, returns false.

Availability: 2.0.0

### Examples

```
SELECT ST_IsEmpty(ST_MakeEmptyRaster(100, 100, 0, 0, 0, 0, 0, 0))
```

st_isempty
f

```
SELECT ST_IsEmpty(ST_MakeEmptyRaster(0, 0, 0, 0, 0, 0, 0, 0))
```

st_isempty
t

**See Also**[ST\\_HasNoBand](#)**9.4.4 ST\_MemSize**

`ST_MemSize` — Returns the amount of space (in bytes) the raster takes.

**Synopsis**

```
integer ST_MemSize(raster rast);
```

**Description**

Returns the amount of space (in bytes) the raster takes.

This is a nice compliment to PostgreSQL built in functions `pg_column_size`, `pg_size_pretty`, `pg_relation_size`, `pg_total_relation_size`.

**Note**

`pg_relation_size` which gives the byte size of a table may return byte size lower than `ST_MemSize`. This is because `pg_relation_size` does not add toasted table contribution and large geometries are stored in TOAST tables. `pg_column_size` might return lower because it returns the compressed size. `pg_total_relation_size` - includes, the table, the toasted tables, and the indexes.

Availability: 2.2.0

**Examples**

```
SELECT ST_MemSize(ST_AsRaster(ST_Buffer(ST_Point(1,5),10,1000),150, 150, '8BUI')) As ←
 rast_mem;

rast_mem

22568
```

**See Also****9.4.5 ST\_MetaData**

`ST_MetaData` — Returns basic meta data about a raster object such as pixel size, rotation (skew), upper, lower left, etc.

**Synopsis**

```
record ST_MetaData(raster rast);
```

**Description**

Returns basic meta data about a raster object such as pixel size, rotation (skew), upper, lower left, etc. Columns returned: `upperleftx` | `upperlefty` | `width` | `height` | `scalex` | `scaley` | `skewx` | `skewy` | `srid` | `numbands`

## Examples

```
SELECT rid, (foo.md).*
FROM (SELECT rid, ST_MetaData(rast) As md
FROM dummy_rast) As foo;
```

rid	upperleftx	upperlefty	width	height	scalex	scaley	skewx	skewy	srid	↔
1	0.5	0.5	10	20	2	3	0	0	0	↔
2	3427927.75	5793244	5	5	0.05	-0.05	0	0	0	↔

## See Also

[ST\\_BandMetaData](#), [ST\\_NumBands](#)

## 9.4.6 ST\_NumBands

`ST_NumBands` — Returns the number of bands in the raster object.

### Synopsis

integer `ST_NumBands`(raster rast);

### Description

Returns the number of bands in the raster object.

### Examples

```
SELECT rid, ST_NumBands(rast) As numbands
FROM dummy_rast;
```

rid	numbands
1	0
2	3

## See Also

[ST\\_Value](#)

## 9.4.7 ST\_PixelHeight

`ST_PixelHeight` — Returns the pixel height in geometric units of the spatial reference system.

### Synopsis

double precision `ST_PixelHeight`(raster rast);

**Description**

Returns the height of a pixel in geometric units of the spatial reference system. In the common case where there is no skew, the pixel height is just the scale ratio between geometric coordinates and raster pixels.

Refer to [ST\\_PixelWidth](#) for a diagrammatic visualization of the relationship.

**Examples: Rasters with no skew**

```
SELECT ST_Height(rast) As rastheight, ST_PixelHeight(rast) As pixheight,
 ST_ScaleX(rast) As scalex, ST_ScaleY(rast) As scaley, ST_SkewX(rast) As skewx,
 ST_SkewY(rast) As skewy
FROM dummy_rast;
```

rastheight	pixheight	scalex	scaley	skewx	skewy
20	3	2	3	0	0
5	0.05	0.05	-0.05	0	0

**Examples: Rasters with skew different than 0**

```
SELECT ST_Height(rast) As rastheight, ST_PixelHeight(rast) As pixheight,
 ST_ScaleX(rast) As scalex, ST_ScaleY(rast) As scaley, ST_SkewX(rast) As skewx,
 ST_SkewY(rast) As skewy
FROM (SELECT ST_SetSKew(rast,0.5,0.5) As rast
 FROM dummy_rast) As skewed;
```

rastheight	pixheight	scalex	scaley	skewx	skewy
20	3.04138126514911	2	3	0.5	0.5
5	0.502493781056044	0.05	-0.05	0.5	0.5

**See Also**

[ST\\_PixelWidth](#), [ST\\_ScaleX](#), [ST\\_ScaleY](#), [ST\\_SkewX](#), [ST\\_SkewY](#)

**9.4.8 ST\_PixelWidth**

**ST\_PixelWidth** — Returns the pixel width in geometric units of the spatial reference system.

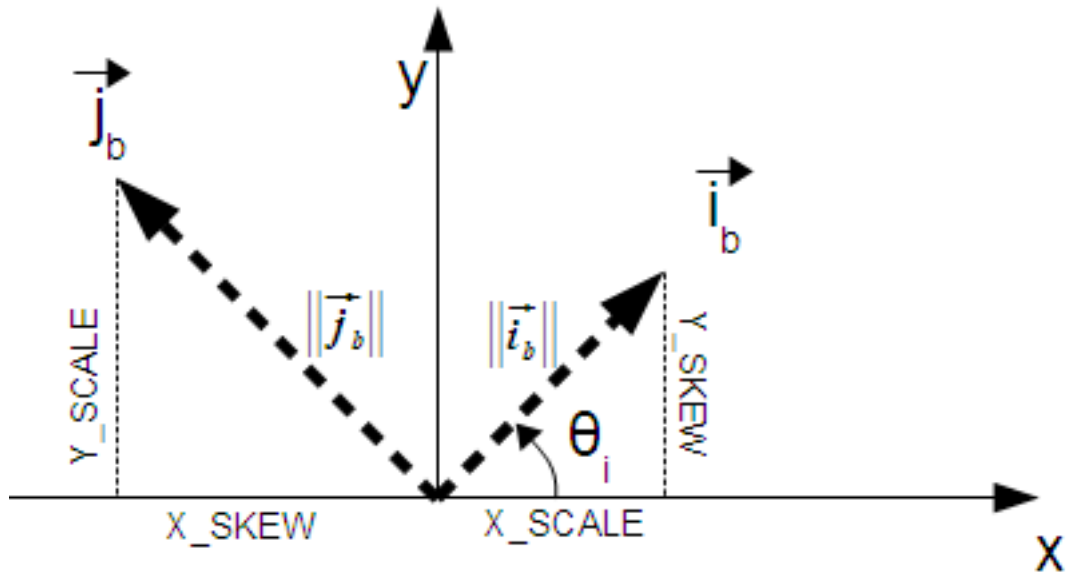

**Synopsis**

```
double precision ST_PixelWidth(raster rast);
```

**Description**

Returns the width of a pixel in geometric units of the spatial reference system. In the common case where there is no skew, the pixel width is just the scale ratio between geometric coordinates and raster pixels.

The following diagram demonstrates the relationship:

Pixel Width: Pixel size in the *i* direction  
 Pixel Height: Pixel size in the *j* direction

**Examples: Rasters with no skew**

```
SELECT ST_Width(rast) As rastwidth, ST_PixelWidth(rast) As pixwidth,
 ST_ScaleX(rast) As scalex, ST_ScaleY(rast) As scaley, ST_SkewX(rast) As skewx,
 ST_SkewY(rast) As skewy
FROM dummy_rast;
```

rastwidth	pixwidth	scalex	scaley	skewx	skewy
10	2	2	3	0	0
5	0.05	0.05	-0.05	0	0

**Examples: Rasters with skew different than 0**

```
SELECT ST_Width(rast) As rastwidth, ST_PixelWidth(rast) As pixwidth,
 ST_ScaleX(rast) As scalex, ST_ScaleY(rast) As scaley, ST_SkewX(rast) As skewx,
 ST_SkewY(rast) As skewy
FROM (SELECT ST_SetSkew(rast,0.5,0.5) As rast
FROM dummy_rast) As skewed;
```

rastwidth	pixwidth	scalex	scaley	skewx	skewy
10	2.06155281280883	2	3	0.5	0.5
5	0.502493781056044	0.05	-0.05	0.5	0.5

**See Also**

**9.4.9 ST\_ScaleX**

ST\_ScaleX — Returns the X component of the pixel width in units of coordinate reference system.

## Synopsis

```
float8 ST_ScaleX(raster rast);
```

## Description

Returns the X component of the pixel width in units of coordinate reference system. Refer to [World File](#) for more details.

Changed: 2.0.0. In WKTRaster versions this was called ST\_PixelSizeX.

## Examples

```
SELECT rid, ST_ScaleX(rast) As rastpixwidth
FROM dummy_rast;
```

rid	rastpixwidth
1	2
2	0.05

## See Also

[ST\\_Width](#)

### 9.4.10 ST\_ScaleY

ST\_ScaleY — Returns the Y component of the pixel height in units of coordinate reference system.

## Synopsis

```
float8 ST_ScaleY(raster rast);
```

## Description

Returns the Y component of the pixel height in units of coordinate reference system. May be negative. Refer to [World File](#) for more details.

Changed: 2.0.0. In WKTRaster versions this was called ST\_PixelSizeY.

## Examples

```
SELECT rid, ST_ScaleY(rast) As rastpixheight
FROM dummy_rast;
```

rid	rastpixheight
1	3
2	-0.05

## See Also

[ST\\_Height](#)

### 9.4.11 ST\_RasterToWorldCoord

`ST_RasterToWorldCoord` — Returns the raster's upper left corner as geometric X and Y (longitude and latitude) given a column and row. Column and row starts at 1.

#### Synopsis

```
record ST_RasterToWorldCoord(raster rast, integer xcolumn, integer yrow);
```

#### Description

Returns the upper left corner as geometric X and Y (longitude and latitude) given a column and row. Returned X and Y are in geometric units of the georeferenced raster. Numbering of column and row starts at 1 but if either parameter is passed a zero, a negative number or a number greater than the respective dimension of the raster, it will return coordinates outside of the raster assuming the raster's grid is applicable outside the raster's bounds.

Availability: 2.1.0

#### Examples

```
-- non-skewed raster
SELECT
 rid,
 (ST_RasterToWorldCoord(rast,1, 1)).*,
 (ST_RasterToWorldCoord(rast,2, 2)).*
FROM dummy_rast

 rid | longitude | latitude | longitude | latitude
-----+-----+-----+-----+-----
 1 | 0.5 | 0.5 | 2.5 | 3.5
 2 | 3427927.75 | 5793244 | 3427927.8 | 5793243.95
```

```
-- skewed raster
SELECT
 rid,
 (ST_RasterToWorldCoord(rast, 1, 1)).*,
 (ST_RasterToWorldCoord(rast, 2, 3)).*
FROM (
 SELECT
 rid,
 ST_SetSkew(rast, 100.5, 0) As rast
 FROM dummy_rast
) As foo

 rid | longitude | latitude | longitude | latitude
-----+-----+-----+-----+-----
 1 | 0.5 | 0.5 | 203.5 | 6.5
 2 | 3427927.75 | 5793244 | 3428128.8 | 5793243.9
```

#### See Also

### 9.4.12 ST\_RasterToWorldCoordX

`ST_RasterToWorldCoordX` — Returns the geometric X coordinate upper left of a raster, column and row. Numbering of columns and rows starts at 1.

## Synopsis

```
float8 ST_RasterToWorldCoordX(raster rast, integer xcolumn);
float8 ST_RasterToWorldCoordX(raster rast, integer xcolumn, integer yrow);
```

## Description

Returns the upper left X coordinate of a raster column row in geometric units of the georeferenced raster. Numbering of columns and rows starts at 1 but if you pass in a negative number or number higher than number of columns in raster, it will give you coordinates outside of the raster file to left or right with the assumption that the skew and pixel sizes are same as selected raster.

### Note

For non-skewed rasters, providing the X column is sufficient. For skewed rasters, the georeferenced coordinate is a function of the `ST_ScaleX` and `ST_SkewX` and row and column. An error will be raised if you give just the X column for a skewed raster.

Changed: 2.1.0 In prior versions, this was called `ST_Raster2WorldCoordX`

## Examples

```
-- non-skewed raster providing column is sufficient
SELECT rid, ST_RasterToWorldCoordX(rast,1) As x1coord,
 ST_RasterToWorldCoordX(rast,2) As x2coord,
 ST_ScaleX(rast) As pixelx
FROM dummy_rast;
```

rid	x1coord	x2coord	pixelx
1	0.5	2.5	2
2	3427927.75	3427927.8	0.05

```
-- for fun lets skew it
SELECT rid, ST_RasterToWorldCoordX(rast, 1, 1) As x1coord,
 ST_RasterToWorldCoordX(rast, 2, 3) As x2coord,
 ST_ScaleX(rast) As pixelx
FROM (SELECT rid, ST_SetSkew(rast, 100.5, 0) As rast FROM dummy_rast) As foo;
```

rid	x1coord	x2coord	pixelx
1	0.5	203.5	2
2	3427927.75	3428128.8	0.05

## See Also

### 9.4.13 ST\_RasterToWorldCoordY

`ST_RasterToWorldCoordY` — Returns the geometric Y coordinate upper left corner of a raster, column and row. Numbering of columns and rows starts at 1.

## Synopsis

```
float8 ST_RasterToWorldCoordY(raster rast, integer yrow);
float8 ST_RasterToWorldCoordY(raster rast, integer xcolumn, integer yrow);
```

## Description

Returns the upper left Y coordinate of a raster column row in geometric units of the georeferenced raster. Numbering of columns and rows starts at 1 but if you pass in a negative number or number higher than number of columns/rows in raster, it will give you coordinates outside of the raster file to left or right with the assumption that the skew and pixel sizes are same as selected raster tile.

### Note

For non-skewed rasters, providing the Y column is sufficient. For skewed rasters, the georeferenced coordinate is a function of the `ST_ScaleY` and `ST_SkewY` and row and column. An error will be raised if you give just the Y row for a skewed raster.

Changed: 2.1.0 In prior versions, this was called `ST_Raster2WorldCoordY`

## Examples

```
-- non-skewed raster providing row is sufficient
SELECT rid, ST_RasterToWorldCoordY(rast,1) As y1coord,
 ST_RasterToWorldCoordY(rast,3) As y2coord,
 ST_ScaleY(rast) As pixely
FROM dummy_rast;
```

rid	y1coord	y2coord	pixely
1	0.5	6.5	3
2	5793244	5793243.9	-0.05

```
-- for fun lets skew it
SELECT rid, ST_RasterToWorldCoordY(rast,1,1) As y1coord,
 ST_RasterToWorldCoordY(rast,2,3) As y2coord,
 ST_ScaleY(rast) As pixely
FROM (SELECT rid, ST_SetSkew(rast,0,100.5) As rast FROM dummy_rast) As foo;
```

rid	y1coord	y2coord	pixely
1	0.5	107	3
2	5793244	5793344.4	-0.05

## See Also

### 9.4.14 ST\_Rotation

`ST_Rotation` — Returns the rotation of the raster in radian.

## Synopsis

```
float8 ST_Rotation(raster rast);
```

**Description**

Returns the uniform rotation of the raster in radian. If a raster does not have uniform rotation, NaN is returned. Refer to [World File](#) for more details.

**Examples**

```
SELECT rid, ST_Rotation(ST_SetScale(ST_SetSkew(rast, sqrt(2)), sqrt(2))) as rot FROM ↵
dummy_rast;
```

rid	rot
1	0.785398163397448
2	0.785398163397448

**See Also**

[ST\\_SetRotation](#), [ST\\_SetScale](#), [ST\\_SetSkew](#)

**9.4.15 ST\_SkewX**

**ST\_SkewX** — Returns the georeference X skew (or rotation parameter).

**Synopsis**

```
float8 ST_SkewX(raster rast);
```

**Description**

Returns the georeference X skew (or rotation parameter). Refer to [World File](#) for more details.

**Examples**

```
SELECT rid, ST_SkewX(rast) As skewx, ST_SkewY(rast) As skewy,
 ST_GeoReference(rast) as georef
FROM dummy_rast;
```

rid	skewx	skewy	georef
1	0	0	2.0000000000 : 0.0000000000 : 0.0000000000 : 3.0000000000 : 0.5000000000 : 0.5000000000 :
2	0	0	0.0500000000 : 0.0000000000 : 0.0000000000 : -0.0500000000 : 3427927.7500000000 : 5793244.0000000000

**See Also**

[ST\\_GeoReference](#), [ST\\_SkewY](#), [ST\\_SetSkew](#)

**9.4.16 ST\_SkewY**

`ST_SkewY` — Returns the georeference Y skew (or rotation parameter).

**Synopsis**

```
float8 ST_SkewY(raster rast);
```

**Description**

Returns the georeference Y skew (or rotation parameter). Refer to [World File](#) for more details.

**Examples**

```
SELECT rid, ST_SkewX(rast) As skewx, ST_SkewY(rast) As skewy,
 ST_GeoReference(rast) as georef
FROM dummy_rast;
```

rid	skewx	skewy	georef
1	0	0	2.0000000000 : 0.0000000000 : 0.0000000000 : 3.0000000000 : 0.5000000000 : 0.5000000000 :
2	0	0	0.0500000000 : 0.0000000000 : 0.0000000000 : -0.0500000000 : 3427927.7500000000 : 5793244.0000000000

**See Also**

[ST\\_GeoReference](#), [ST\\_SkewX](#), [ST\\_SetSkew](#)

**9.4.17 ST\_SRID**

`ST_SRID` — Returns the spatial reference identifier of the raster as defined in `spatial_ref_sys` table.

**Synopsis**

```
integer ST_SRID(raster rast);
```

## Description

Returns the spatial reference identifier of the raster object as defined in the `spatial_ref_sys` table.

### Note

From PostGIS 2.0+ the srid of a non-georeferenced raster/geometry is 0 instead of the prior -1.

## Examples

```
SELECT ST_SRID(rast) As srid
FROM dummy_rast WHERE rid=1;
```

```
srid

0
```

## See Also

Section [4.3.1](#), [ST\\_SRID](#)

## 9.4.18 ST\_Summary

`ST_Summary` — Returns a text summary of the contents of the raster.

### Synopsis

```
text ST_Summary(raster rast);
```

### Description

Returns a text summary of the contents of the raster.

Availability: 2.1.0

## Examples

```
SELECT ST_Summary(
 ST_AddBand(
 ST_AddBand(
 ST_AddBand(
 ST_MakeEmptyRaster(10, 10, 0, 0, 1, -1, 0, 0, 0)
 , 1, '8BUI', 1, 0
)
 , 2, '32BF', 0, -9999
)
 , 3, '16BSI', 0, NULL
)
);
```

```
st_summary

```

```
Raster of 10x10 pixels has 3 bands and extent of BOX(0 -10,10 0)+
 band 1 of pixtype 8BUI is in-db with NODATA value of 0 +
 band 2 of pixtype 32BF is in-db with NODATA value of -9999 +
 band 3 of pixtype 16BSI is in-db with no NODATA value
(1 row)
```

**See Also**

**9.4.19 ST\_UpperLeftX**

`ST_UpperLeftX` — Returns the upper left X coordinate of raster in projected spatial ref.

**Synopsis**

```
float8 ST_UpperLeftX(raster rast);
```

**Description**

Returns the upper left X coordinate of raster in projected spatial ref.

**Examples**

```
SELECT rid, ST_UpperLeftX(rast) As ulx
FROM dummy_rast;
```

rid	ulx
1	0.5
2	3427927.75

**See Also**

[ST\\_UpperLeftY](#), [ST\\_GeoReference](#), [Box3D](#)

**9.4.20 ST\_UpperLeftY**

`ST_UpperLeftY` — Returns the upper left Y coordinate of raster in projected spatial ref.

**Synopsis**

```
float8 ST_UpperLeftY(raster rast);
```

**Description**

Returns the upper left Y coordinate of raster in projected spatial ref.

**Examples**

```
SELECT rid, ST_UpperLeftY(rast) As uly
FROM dummy_rast;
```

```
rid | uly
-----+-----
 1 | 0.5
 2 | 5793244
```

**See Also**

[ST\\_UpperLeftX](#), [ST\\_GeoReference](#), [Box3D](#)

**9.4.21 ST\_Width**

`ST_Width` — Returns the width of the raster in pixels.

**Synopsis**

integer `ST_Width`(raster rast);

**Description**

Returns the width of the raster in pixels.

**Examples**

```
SELECT ST_Width(rast) As rastwidth
FROM dummy_rast WHERE rid=1;
```

```
rastwidth

10
```

**See Also**

[ST\\_Height](#)

**9.4.22 ST\_WorldToRasterCoord**

`ST_WorldToRasterCoord` — Returns the upper left corner as column and row given geometric X and Y (longitude and latitude) or a point geometry expressed in the spatial reference coordinate system of the raster.

**Synopsis**

record `ST_WorldToRasterCoord`(raster rast, geometry pt);  
 record `ST_WorldToRasterCoord`(raster rast, double precision longitude, double precision latitude);

**Description**

Returns the upper left corner as column and row given geometric X and Y (longitude and latitude) or a point geometry. This function works regardless of whether or not the geometric X and Y or point geometry is outside the extent of the raster. Geometric X and Y must be expressed in the spatial reference coordinate system of the raster.

Availability: 2.1.0

**Examples**

```
SELECT
 rid,
 (ST_WorldToRasterCoord(rast,3427927.8,20.5)).*,
 (ST_WorldToRasterCoord(rast,ST_GeomFromText('POINT(3427927.8 20.5)',ST_SRID(rast)))).*
FROM dummy_rast;
```

rid	columnx	rowy	columnx	rowy
1	1713964	7	1713964	7
2	2	115864471	2	115864471

**See Also**

**9.4.23 ST\_WorldToRasterCoordX**

**ST\_WorldToRasterCoordX** — Returns the column in the raster of the point geometry (pt) or a X and Y world coordinate (xw, yw) represented in world spatial reference system of raster.

**Synopsis**

```
integer ST_WorldToRasterCoordX(raster rast, geometry pt);
integer ST_WorldToRasterCoordX(raster rast, double precision xw);
integer ST_WorldToRasterCoordX(raster rast, double precision xw, double precision yw);
```

**Description**

Returns the column in the raster of the point geometry (pt) or a X and Y world coordinate (xw, yw). A point, or (both xw and yw world coordinates are required if a raster is skewed). If a raster is not skewed then xw is sufficient. World coordinates are in the spatial reference coordinate system of the raster.

Changed: 2.1.0 In prior versions, this was called `ST_World2RasterCoordX`

**Examples**

```
SELECT rid, ST_WorldToRasterCoordX(rast,3427927.8) As xcoord,
 ST_WorldToRasterCoordX(rast,3427927.8,20.5) As xcoord_xwyw,
 ST_WorldToRasterCoordX(rast,ST_GeomFromText('POINT(3427927.8 20.5)',ST_SRID(rast))) As ←
 ptxcoord
FROM dummy_rast;
```

rid	xcoord	xcoord_xwyw	ptxcoord
1	1713964	1713964	1713964
2	1	1	1

**See Also**

[ST\\_RasterToWorldCoordX](#), [ST\\_RasterToWorldCoordY](#), [ST\\_SRID](#)

**9.4.24 ST\_WorldToRasterCoordY**

`ST_WorldToRasterCoordY` — Returns the row in the raster of the point geometry (pt) or a X and Y world coordinate (xw, yw) represented in world spatial reference system of raster.

**Synopsis**

```
integer ST_WorldToRasterCoordY(raster rast, geometry pt);
integer ST_WorldToRasterCoordY(raster rast, double precision xw);
integer ST_WorldToRasterCoordY(raster rast, double precision xw, double precision yw);
```

**Description**

Returns the row in the raster of the point geometry (pt) or a X and Y world coordinate (xw, yw). A point, or (both xw and yw world coordinates are required if a raster is skewed). If a raster is not skewed then xw is sufficient. World coordinates are in the spatial reference coordinate system of the raster.

Changed: 2.1.0 In prior versions, this was called `ST_World2RasterCoordY`

**Examples**

```
SELECT rid, ST_WorldToRasterCoordY(rast,20.5) As ycoord,
 ST_WorldToRasterCoordY(rast,3427927.8,20.5) As ycoord_xwyw,
 ST_WorldToRasterCoordY(rast,ST_GeomFromText('POINT(3427927.8 20.5)',ST_SRID(rast))) As ←
 ptycoord
FROM dummy_rast;
```

rid	ycoord	ycoord_xwyw	ptycoord
1	7	7	7
2	115864471	115864471	115864471

**See Also**

[ST\\_RasterToWorldCoordX](#), [ST\\_RasterToWorldCoordY](#), [ST\\_SRID](#)

**9.5 Raster Band Accessors****9.5.1 ST\_BandMetaData**

`ST_BandMetaData` — Returns basic meta data for a specific raster band. band num 1 is assumed if none-specified.

**Synopsis**

```
record ST_BandMetaData(raster rast, integer bandnum=1);
```

**Description**

Returns basic meta data about a raster band. Columns returned pixeltype | nodatavalue | isoutdb | path.

**Note**

If raster contains no bands then an error is thrown.

**Note**

If band has no NODATA value, nodatavalue will be NULL.

**Examples**

```
SELECT rid, (foo.md).*
 FROM (SELECT rid, ST_BandMetaData(rast,1) As md
 FROM dummy_rast WHERE rid=2) As foo;
```

rid	pixeltype	nodatavalue	isoutdb	path
2	8BUI	0	f	

**See Also**

[ST\\_MetaData](#), [ST\\_BandPixelType](#)

**9.5.2 ST\_BandNoDataValue**

`ST_BandNoDataValue` — Returns the value in a given band that represents no data. If no band num 1 is assumed.

**Synopsis**

double precision `ST_BandNoDataValue`(raster rast, integer bandnum=1);

**Description**

Returns the value that represents no data for the band

**Examples**

```
SELECT ST_BandNoDataValue(rast,1) As bnval1,
 ST_BandNoDataValue(rast,2) As bnval2, ST_BandNoDataValue(rast,3) As bnval3
 FROM dummy_rast
 WHERE rid = 2;
```

bnval1	bnval2	bnval3
0	0	0

**See Also**[ST\\_NumBands](#)**9.5.3 ST\_BandIsNoData**

ST\_BandIsNoData — Returns true if the band is filled with only nodata values.

**Synopsis**

boolean **ST\_BandIsNoData**(raster rast, integer band, boolean forceChecking=true);

boolean **ST\_BandIsNoData**(raster rast, boolean forceChecking=true);

**Description**

Returns true if the band is filled with only nodata values. Band 1 is assumed if not specified. If the last argument is TRUE, the entire band is checked pixel by pixel. Otherwise, the function simply returns the value of the isnodata flag for the band. The default value for this parameter is FALSE, if not specified.

Availability: 2.0.0

**Note**

If the flag is dirty (this is, the result is different using TRUE as last parameter and not using it) you should update the raster to set this flag to true, by using [ST\\_SetBandIsNodata\(\)](#), or [ST\\_SetBandNodataValue\(\)](#) with TRUE as last argument. See [ST\\_SetBandIsNoData](#).

**Examples**

```
-- Create dummy table with one raster column
create table dummy_rast (rid integer, rast raster);

-- Add raster with two bands, one pixel/band. In the first band, nodatavalue = pixel value ←
= 3.
-- In the second band, nodatavalue = 13, pixel value = 4
insert into dummy_rast values(1,

**9.5.4 ST\_BandPath**

`ST_BandPath` — Returns system file path to a band stored in file system. If no bandnum specified, 1 is assumed.

**Synopsis**

```
text ST_BandPath(raster rast, integer bandnum=1);
```

**Description**

Returns system file path to a band. Throws an error if called with an in db band.

**Examples****See Also****9.5.5 ST\_BandPixelType**

`ST_BandPixelType` — Returns the type of pixel for given band. If no bandnum specified, 1 is assumed.

**Synopsis**

```
text ST_BandPixelType(raster rast, integer bandnum=1);
```

**Description**

Returns the value that represents no data for the band

There are 11 pixel types. Pixel Types supported are as follows:

- 1BB - 1-bit boolean
- 2BUI - 2-bit unsigned integer
- 4BUI - 4-bit unsigned integer
- 8BSI - 8-bit signed integer
- 8BUI - 8-bit unsigned integer
- 16BSI - 16-bit signed integer
- 16BUI - 16-bit unsigned integer
- 32BSI - 32-bit signed integer
- 32BUI - 32-bit unsigned integer
- 32BF - 32-bit float
- 64BF - 64-bit float

**Examples**

```
SELECT ST_BandPixelType(rast,1) As btype1,
 ST_BandPixelType(rast,2) As btype2, ST_BandPixelType(rast,3) As btype3
FROM dummy_rast
WHERE rid = 2;
```

btype1	btype2	btype3
8BUI	8BUI	8BUI

**9.5.6 ST\_HasNoBand**

**ST\_HasNoBand** — Returns true if there is no band with given band number. If no band number is specified, then band number 1 is assumed.

**Synopsis**

boolean **ST\_HasNoBand**(raster rast, integer bandnum=1);

**Description**

Returns true if there is no band with given band number. If no band number is specified, then band number 1 is assumed.

Availability: 2.0.0

## Examples

```
SELECT rid, ST_HasNoBand(rast) As hb1, ST_HasNoBand(rast,2) as hb2,
ST_HasNoBand(rast,4) as hb4, ST_NumBands(rast) As numbands
FROM dummy_rast;
```

rid	hb1	hb2	hb4	numbands
1	t	t	t	0
2	f	f	t	3

## 9.6 Raster Pixel Accessors and Setters

### 9.6.1 ST\_PixelAsPolygon

`ST_PixelAsPolygon` — Returns the polygon geometry that bounds the pixel for a particular row and column.

#### Synopsis

geometry `ST_PixelAsPolygon`(raster rast, integer columnx, integer rowy);

#### Description

Returns the polygon geometry that bounds the pixel for a particular row and column.

Availability: 2.0.0

#### Examples

```
-- get raster pixel polygon
SELECT i,j, ST_AsText(ST_PixelAsPolygon(foo.rast, i,j)) As blpgeom
FROM dummy_rast As foo
 CROSS JOIN generate_series(1,2) As i
 CROSS JOIN generate_series(1,1) As j
WHERE rid=2;
```

i	j	blpgeom
1	1	POLYGON((3427927.75 5793244,3427927.8 5793244,3427927.8 5793243.95,...
2	1	POLYGON((3427927.8 5793244,3427927.85 5793244,3427927.85 5793243.95, ..

## 9.6.2 ST\_PixelAsPolygons

`ST_PixelAsPolygons` — Returns the polygon geometry that bounds every pixel of a raster band along with the value, the X and the Y raster coordinates of each pixel.

### Synopsis

```
setof record ST_PixelAsPolygons(raster rast, integer band=1, boolean exclude_nodata_value=TRUE);
```

### Description

Returns the polygon geometry that bounds every pixel of a raster band along with the value (double precision), the X and the Y raster coordinates (integers) of each pixel.

#### Note

`ST_PixelAsPolygons` returns one polygon geometry for every pixel. This is different than `ST_DumpAsPolygons` where each geometry represents one or more pixels with the same pixel value.

#### Note

When `exclude_nodata_value = TRUE`, only those pixels whose values are not NODATA are returned as polygons.

Availability: 2.0.0

Enhanced: 2.1.0 `exclude_nodata_value` optional argument was added.

Changed: 2.1.1 Changed behavior of `exclude_nodata_value`.

### Examples

```
-- get raster pixel polygon
SELECT (gv).x, (gv).y, (gv).val, ST_AsText((gv).geom) geom
FROM (SELECT ST_PixelAsPolygons(
 ST_SetValue(ST_SetValue(ST_AddBand(ST_MakeEmptyRaster(2, 2, 0, 0, 0.001, ←
 -0.001, 0.001, 0.001, 4269),
 '8BUI'::text, 1, 0),
 2, 2, 10),
 1, 1, NULL)
) gv
) foo;
```

x	y	val	geom
1	1		POLYGON((0 0,0.001 0.001,0.002 0,0.001 -0.001,0 0))
1	2	1	POLYGON((0.001 -0.001,0.002 0,0.003 -0.001,0.002 -0.002,0.001 -0.001))
2	1	1	POLYGON((0.001 0.001,0.002 0.002,0.003 0.001,0.002 0,0.001 0.001))
2	2	10	POLYGON((0.002 0,0.003 0.001,0.004 0,0.003 -0.001,0.002 0))

### 9.6.3 ST\_PixelAsPoint

`ST_PixelAsPoint` — Returns a point geometry of the pixel's upper-left corner.

#### Synopsis

geometry `ST_PixelAsPoint`(raster rast, integer columnx, integer rowy);

#### Description

Returns a point geometry of the pixel's upper-left corner.

Availability: 2.1.0

#### Examples

```
SELECT ST_AsText(ST_PixelAsPoint(rast, 1, 1)) FROM dummy_rast WHERE rid = 1;

 st_astext

POINT(0.5 0.5)
```

#### See Also

### 9.6.4 ST\_PixelAsPoints

`ST_PixelAsPoints` — Returns a point geometry for each pixel of a raster band along with the value, the X and the Y raster coordinates of each pixel. The coordinates of the point geometry are of the pixel's upper-left corner.

#### Synopsis

geometry `ST_PixelAsPoints`(raster rast, integer band=1, boolean exclude\_nodata\_value=TRUE);

#### Description

Returns a point geometry for each pixel of a raster band along with the value, the X and the Y raster coordinates of each pixel. The coordinates of the point geometry are of the pixel's upper-left corner.

#### Note

When `exclude_nodata_value = TRUE`, only those pixels whose values are not NODATA are returned as points.

---

Availability: 2.1.0

Changed: 2.1.1 Changed behavior of `exclude_nodata_value`.

---

## Examples

```

## 9.6.7 ST\_Value

**ST\_Value** — Returns the value of a given band in a given columnx, rowy pixel or at a particular geometric point. Band numbers start at 1 and assumed to be 1 if not specified. If `exclude_nodata_value` is set to false, then all pixels include nodata pixels are considered to intersect and return value. If `exclude_nodata_value` is not passed in then reads it from metadata of raster.

### Synopsis

```

double precision ST_Value(raster rast, geometry pt, boolean exclude_nodata_value=true);
double precision ST_Value(raster rast, integer band, geometry pt, boolean exclude_nodata_value=true);
double precision ST_Value(raster rast, integer x, integer y, boolean exclude_nodata_value=true);
double precision ST_Value(raster rast, integer band, integer x, integer y, boolean exclude_nodata_value=true);

```

### Description

Returns the value of a given band in a given columnx, rowy pixel or at a given geometry point. Band numbers start at 1 and band is assumed to be 1 if not specified. If `exclude_nodata_value` is set to true, then only non nodata pixels are considered. If `exclude_nodata_value` is set to false, then all pixels are considered.

Enhanced: 2.0.0 `exclude_nodata_value` optional argument was added.

### Examples

```

-- get raster values at particular postgis geometry points
-- the srid of your geometry should be same as for your raster
SELECT rid, ST_Value(rast, foo.pt_geom) As b1pval, ST_Value(rast, 2, foo.pt_geom) As b2pval
FROM dummy_rast CROSS JOIN (SELECT ST_SetSRID(ST_Point(3427927.77, 5793243.76), 0) As ←
 pt_geom) As foo
WHERE rid=2;

```

```

rid | b1pval | b2pval
-----+-----+-----
 2 | 252 | 79

```

```

-- general fictitious example using a real table
SELECT rid, ST_Value(rast, 3, sometable.geom) As b3pval
FROM sometable
WHERE ST_Intersects(rast, sometable.geom);

```

```
SELECT rid, ST_Value(rast, 1, 1, 1) As b1pval,
 ST_Value(rast, 2, 1, 1) As b2pval, ST_Value(rast, 3, 1, 1) As b3pval
FROM dummy_rast
WHERE rid=2;
```

rid	b1pval	b2pval	b3pval
2	253	78	70

```
--- Get all values in bands 1,2,3 of each pixel --
SELECT x, y, ST_Value(rast, 1, x, y) As b1val,

## 9.6.8 ST\_NearestValue

**ST\_NearestValue** — Returns the nearest non-NODATA value of a given band's pixel specified by a columnx and rowy or a geometric point expressed in the same spatial reference coordinate system as the raster.

### Synopsis

```
double precision ST_NearestValue(raster rast, integer bandnum, geometry pt, boolean exclude_nodata_value=true);
double precision ST_NearestValue(raster rast, geometry pt, boolean exclude_nodata_value=true);
double precision ST_NearestValue(raster rast, integer bandnum, integer columnx, integer rowy, boolean exclude_nodata_value=true);
double precision ST_NearestValue(raster rast, integer columnx, integer rowy, boolean exclude_nodata_value=true);
```

### Description

Returns the nearest non-NODATA value of a given band in a given columnx, rowy pixel or at a specific geometric point. If the columnx, rowy pixel or the pixel at the specified geometric point is NODATA, the function will find the nearest pixel to the columnx, rowy pixel or geometric point whose value is not NODATA.

Band numbers start at 1 and bandnum is assumed to be 1 if not specified. If `exclude_nodata_value` is set to false, then all pixels include nodata pixels are considered to intersect and return value. If `exclude_nodata_value` is not passed in then reads it from metadata of raster.

Availability: 2.1.0

#### Note

`ST_NearestValue` is a drop-in replacement for `ST_Value`.

### Examples

```
-- pixel 2x2 has value
SELECT
 ST_Value(rast, 2, 2) AS value,
 ST_NearestValue(rast, 2, 2) AS nearestvalue
FROM (
 SELECT
 ST_SetValue(
 ST_SetValue(
 ST_SetValue(
 ST_SetValue(
 ST_SetValue(
 ST_AddBand(
 ST_MakeEmptyRaster(5, 5, -2, 2, 1, -1, 0, 0, 0),
 '8BUI'::text, 1, 0
),
),
),
),
),
 1, 1, 0.
```

```

),
 2, 3, 0.
),
 3, 5, 0.
),
4, 2, 0.
),
5, 4, 0.
) AS rast
) AS foo

```

value	nearestvalue
1	1

```

-- pixel 2x3 is NODATA
SELECT
 ST_Value(rast, 2, 3) AS value,
 ST_NearestValue(rast, 2, 3) AS nearestvalue
FROM (
 SELECT
 ST_SetValue(
 ST_SetValue(
 ST_SetValue(
 ST_SetValue(
 ST_SetValue(
 ST_AddBand(
 ST_MakeEmptyRaster(5, 5, -2, 2, 1, -1, 0, 0, 0),
 '8BUI'::text, 1, 0
),
 1, 1, 0.
),
 2, 3, 0.
),
 3, 5, 0.
),
 4, 2, 0.
),

## 9.6.9 ST\_Neighborhood

**ST\_Neighborhood** — Returns a 2-D double precision array of the non-NODATA values around a given band's pixel specified by either a columnX and rowY or a geometric point expressed in the same spatial reference coordinate system as the raster.

## Synopsis

```
double precision[][] ST_Neighborhood(raster rast, integer bandnum, integer columnX, integer rowY, integer distanceX, integer
distanceY, boolean exclude_nodata_value=true);
double precision[][] ST_Neighborhood(raster rast, integer columnX, integer rowY, integer distanceX, integer distanceY, boolean
exclude_nodata_value=true);
double precision[][] ST_Neighborhood(raster rast, integer bandnum, geometry pt, integer distanceX, integer distanceY, boolean
exclude_nodata_value=true);
double precision[][] ST_Neighborhood(raster rast, geometry pt, integer distanceX, integer distanceY, boolean exclude_nodata_value=true);
```

## Description

Returns a 2-D double precision array of the non-NODATA values around a given band's pixel specified by either a columnX and rowY or a geometric point expressed in the same spatial reference coordinate system as the raster. The distanceX and distanceY parameters define the number of pixels around the specified pixel in the X and Y axes, e.g. I want all values within 3 pixel distance along the X axis and 2 pixel distance along the Y axis around my pixel of interest. The center value of the 2-D array will be the value at the pixel specified by the columnX and rowY or the geometric point.

Band numbers start at 1 and bandnum is assumed to be 1 if not specified. If exclude\_nodata\_value is set to false, then all pixels include nodata pixels are considered to intersect and return value. If exclude\_nodata\_value is not passed in then reads it from metadata of raster.

### Note

The number of elements along each axis of the returning 2-D array is  $2 * (\text{distanceX}|\text{distanceY}) + 1$ . So for a distanceX and distanceY of 1, the returning array will be 3x3.

### Note

The 2-D array output can be passed to any of the raster processing builtin functions, e.g. ST\_Min4ma, ST\_Sum4ma, ST\_Mean4ma.

### 9.6.10 ST\_SetValue

**ST\_SetValue** — Returns modified raster resulting from setting the value of a given band in a given columnx, rowy pixel or the pixels that intersect a particular geometry. Band numbers start at 1 and assumed to be 1 if not specified.

#### Synopsis

```
raster ST_SetValue(raster rast, integer bandnum, geometry geom, double precision newvalue);
raster ST_SetValue(raster rast, geometry geom, double precision newvalue);
raster ST_SetValue(raster rast, integer bandnum, integer columnx, integer rowy, double precision newvalue);
raster ST_SetValue(raster rast, integer columnx, integer rowy, double precision newvalue);
```

#### Description

Returns modified raster resulting from setting the specified pixels' values to new value for the designed band given the raster's row and column or a geometry. If no band is specified, then band 1 is assumed.

Enhanced: 2.1.0 Geometry variant of `ST_SetValue()` now supports any geometry type, not just point. The geometry variant is a wrapper around the `geomval[]` variant of `ST_SetValues()`

#### Examples

```
-- Geometry example
SELECT (foo.geomval).val, ST_AsText(ST_Union((foo.geomval).geom))
FROM (SELECT ST_DumpAsPolygons(
 ST_SetValue(rast,1,
 ST_Point(3427927.75, 5793243.95),
 50)
) As geomval
FROM dummy_rast
where rid = 2) As foo
WHERE (foo.geomval).val < 250
GROUP BY (foo.geomval).val;
```

val	st_astext
50	POLYGON((3427927.75 5793244,3427927.75 5793243.95,3427927.8 579324 ...
249	POLYGON((3427927.95 5793243.95,3427927.95 5793243.85,3427928 57932 ...

```
-- Store the changed raster --
UPDATE dummy_rast SET rast = ST_SetValue(rast,1, ST_Point(3427927.75, 5793243.95),100)
WHERE rid = 2 ;
```

### 9.6.11 ST\_SetValues

**ST\_SetValues** — Returns modified raster resulting from setting the values of a given band.

## Synopsis

```
raster ST_SetValues(raster rast, integer nband, integer columnx, integer rowy, double precision[][] newvalueset, boolean[][] noset=NULL, boolean keepnodata=FALSE);
raster ST_SetValues(raster rast, integer nband, integer columnx, integer rowy, double precision[][] newvalueset, double precision nosetvalue, boolean keepnodata=FALSE);
raster ST_SetValues(raster rast, integer nband, integer columnx, integer rowy, integer width, integer height, double precision newvalue, boolean keepnodata=FALSE);
raster ST_SetValues(raster rast, integer columnx, integer rowy, integer width, integer height, double precision newvalue, boolean keepnodata=FALSE);
raster ST_SetValues(raster rast, integer nband, geomval[] geomvalset, boolean keepnodata=FALSE);
```

## Description

Returns modified raster resulting from setting specified pixels to new value(s) for the designated band.

If `keepnodata` is `TRUE`, those pixels whose values are `NODATA` will not be set with the corresponding value in `newvalue set`.

For Variant 1, the specific pixels to be set are determined by the `columnx`, `rowy` pixel coordinates and the dimensions of the `newvalueset` array. `noset` can be used to prevent pixels with values present in `newvalueset` from being set (due to PostgreSQL not permitting ragged/jagged arrays). See example Variant 1.

Variant 2 is like Variant 1 but with a simple double precision `nosetvalue` instead of a boolean `noset` array. Elements in `newvalueset` with the `nosetvalue` value will be skipped. See example Variant 2.

For Variant 3, the specific pixels to be set are determined by the `columnx`, `rowy` pixel coordinates, `width` and `height`. See example Variant 3.

Variant 4 is the same as Variant 3 with the exception that it assumes that the first band's pixels of `rast` will be set.

For Variant 5, an array of `geomval` is used to determine the specific pixels to be set. If all the geometries in the array are of type `POINT` or `MULTIPOINT`, the function uses a shortcut where the longitude and latitude of each point is used to set a pixel directly. Otherwise, the geometries are converted to rasters and then iterated through in one pass. See example Variant 5.

Availability: 2.1.0

3	3	9

**Examples: Variant 5**

```

WITH foo AS (
 SELECT 1 AS rid, ST_AddBand(ST_MakeEmptyRaster(5, 5, 0, 0, 1, -1, 0, 0, 0), 1, '8BUI', 0, 0) AS rast
), bar AS (
 SELECT 1 AS gid, 'SRID=0;POINT(2.5 -2.5)::geometry geom UNION ALL
 SELECT 2 AS gid, 'SRID=0;POLYGON((1 -1, 4 -1, 4 -4, 1 -4, 1 -1))::geometry geom UNION ALL
 SELECT 3 AS gid, 'SRID=0;POLYGON((0 0, 5 0, 5 -1, 1 -1, 1 -4, 0 -4, 0 0))::geometry geom UNION ALL
 SELECT 4 AS gid, 'SRID=0;MULTIPOINT(0 0, 4 4, 4 -4)::geometry
)
SELECT
 rid, gid, ST_DumpValues(ST_SetValue(rast, 1, geom, gid))
FROM foo t1
CROSS JOIN bar t2
ORDER BY rid, gid;

```

rid	gid	st_dumpvalues
1	1	(1, "{ {NULL, NULL, NULL, NULL, NULL}, {NULL, NULL, NULL, NULL, NULL}, {NULL, NULL, 1, NULL, NULL}, {NULL, NULL, NULL, NULL, NULL}, {NULL, NULL, NULL, NULL, NULL} }")
1	2	(1, "{ {NULL, NULL, NULL, NULL, NULL}, {NULL, 2, 2, 2, NULL}, {NULL, 2, 2, 2, NULL}, {NULL, 2, 2, 2, NULL}, {NULL, NULL, NULL, NULL, NULL} }")
1	3	(1, "{ {3, 3, 3, 3, 3}, {3, NULL, NULL, NULL, NULL}, {3, NULL, NULL, NULL, NULL}, {3, NULL, NULL, NULL, NULL}, {NULL, NULL, NULL, NULL, NULL} }")
1	4	(1, "{ {4, NULL, NULL, NULL, NULL}, {NULL, NULL, NULL, NULL, NULL}, {NULL, NULL, NULL, NULL, NULL}, {NULL, NULL, NULL, NULL, 4} }")

(4 rows)

The following shows that geomvals later in the array can overwrite prior geomvals

```

WITH foo AS (
 SELECT 1 AS rid, ST_AddBand(ST_MakeEmptyRaster(5, 5, 0, 0, 1, -1, 0, 0, 0), 1, '8BUI', 0, 0) AS rast
), bar AS (
 SELECT 1 AS gid, 'SRID=0;POINT(2.5 -2.5)::geometry geom UNION ALL
 SELECT 2 AS gid, 'SRID=0;POLYGON((1 -1, 4 -1, 4 -4, 1 -4, 1 -1))::geometry geom UNION ALL

```

```

SELECT 3 AS gid, 'SRID=0;POLYGON((0 0, 5 0, 5 -1, 1 -1, 1 -4, 0 -4, 0 0))'::geometry geom ←
 UNION ALL
SELECT 4 AS gid, 'SRID=0;MULTIPOINT(0 0, 4 4, 4 -4)'::geometry
)
SELECT
 t1.rid, t2.gid, t3.gid, ST_DumpValues(ST_SetValues(rast, 1, ARRAY[ROW(t2.geom, t2.gid), ←
 ROW(t3.geom, t3.gid)]::geomval[]))
FROM foo t1
CROSS JOIN bar t2
CROSS JOIN bar t3
WHERE t2.gid = 1
 AND t3.gid = 2
ORDER BY t1.rid, t2.gid, t3.gid;

```

rid	gid	gid	st_dumpvalues
1	1	2	(1, "{NULL, NULL, NULL, NULL, NULL}, {NULL, 2, 2, 2, NULL}, {NULL, 2, 2, 2, NULL}, { ← NULL, 2, 2, 2, NULL}, {NULL, NULL, NULL, NULL, NULL}")

(1 row)

This example is the opposite of the prior example

```

WITH foo AS (

### 9.6.12 ST\_DumpValues

**ST\_DumpValues** — Get the values of the specified band as a 2-dimension array.

## Synopsis

```
setof record ST_DumpValues(raster rast , integer[] nband=NULL , boolean exclude_nodata_value=true);
double precision[][] ST_DumpValues(raster rast , integer nband , boolean exclude_nodata_value=true);
```

## Description

Get the values of the specified band as a 2-dimension array (first index is row, second is column). If nband is NULL or not provided, all raster bands are processed.

Availability: 2.1.0

## Examples

```
WITH foo AS (
 SELECT ST_AddBand(ST_AddBand(ST_AddBand(ST_MakeEmptyRaster(3, 3, 0, 0, 1, -1, 0, 0, 0), ←
 1, '8BUI', 1, 0), 2, '32BF', 3, -9999), 3, '16BSI', 0, 0) AS rast
)
SELECT
 (ST_DumpValues(rast)).*
FROM foo;
```

nband	valarray
1	{{1,1,1},{1,1,1},{1,1,1}}
2	{{3,3,3},{3,3,3},{3,3,3}}
3	{{NULL,NULL,NULL},{NULL,NULL,NULL},{NULL,NULL,NULL}}

(3 rows)

```
WITH foo AS (
 SELECT ST_AddBand(ST_AddBand(ST_AddBand(ST_MakeEmptyRaster(3, 3, 0, 0, 1, -1, 0, 0, 0), ←

### 9.6.13 ST\_PixelOfValue

ST\_PixelOfValue — Get the columnx, rowy coordinates of the pixel whose value equals the search value.

#### Synopsis

```
setof record ST_PixelOfValue(raster rast , integer nband , double precision[] search , boolean exclude_nodata_value=true);
setof record ST_PixelOfValue(raster rast , double precision[] search , boolean exclude_nodata_value=true);
setof record ST_PixelOfValue(raster rast , integer nband , double precision search , boolean exclude_nodata_value=true);
setof record ST_PixelOfValue(raster rast , double precision search , boolean exclude_nodata_value=true);
```

#### Description

Get the columnx, rowy coordinates of the pixel whose value equals the search value. If no band is specified, then band 1 is assumed.

Availability: 2.1.0

#### Examples

```
SELECT
 (pixels).*
FROM (
 SELECT
 ST_PixelOfValue(
 ST_SetValue(
 ST_SetValue(
 ST_SetValue(
 ST_SetValue(
 ST_SetValue(
 ST_SetValue(

## 9.7 Raster Editors

### 9.7.1 ST\_SetGeoReference

`ST_SetGeoReference` — Set Georeference 6 georeference parameters in a single call. Numbers should be separated by white space. Accepts inputs in GDAL or ESRI format. Default is GDAL.

#### Synopsis

```

raster ST_SetGeoReference(raster rast, text georefcoords, text format=GDAL);
raster ST_SetGeoReference(raster rast, double precision upperleftx, double precision upperlefty, double precision scalex, double precision scaley, double precision skewx, double precision skewy);

```

#### Description

Set Georeference 6 georeference parameters in a single call. Accepts inputs in 'GDAL' or 'ESRI' format. Default is GDAL. If 6 coordinates are not provided will return null.

Difference between format representations is as follows:

GDAL:

```
scalex skewy skewx scaley upperleftx upperlefty
```

ESRI:

```
scalex skewy skewx scaley upperleftx + scalex*0.5 upperlefty + scaley*0.5
```

#### Note

If the raster has out-db bands, changing the georeference may result in incorrect access of the band's externally stored data.

Enhanced: 2.1.0 Addition of `ST_SetGeoReference(raster, double precision, ...)` variant

#### Examples

```
WITH foo AS (
 SELECT ST_MakeEmptyRaster(5, 5, 0, 0, 1, -1, 0, 0, 0) AS rast
)
SELECT
 0 AS rid, (ST_Metadata(rast)).*
FROM foo
UNION ALL
SELECT
 1, (ST_Metadata(ST_SetGeoReference(rast, '10 0 0 -10 0.1 0.1', 'GDAL'))).*
FROM foo
UNION ALL
SELECT
 2, (ST_Metadata(ST_SetGeoReference(rast, '10 0 0 -10 5.1 -4.9', 'ESRI'))).*
FROM foo
UNION ALL
SELECT
 3, (ST_Metadata(ST_SetGeoReference(rast, 1, 1, 10, -10, 0.001, 0.001))).*
FROM foo
```

rid	upperleftx skewy	srid	numbands	upperlefty	width	height	scalex	scaley	skewx	skewy
0	0	0	0	0	5	5	1	-1	0	0
1	0.1	0	0	0.1	5	5	10	-10	0	0
2	0.09999999999999996	0	0	0.09999999999999996	5	5	10	-10	0	0
3	0.001	0	0	1	5	5	10	-10	0.001	0

**See Also**

**9.7.2 ST\_SetRotation**

ST\_SetRotation — Set the rotation of the raster in radian.

**Synopsis**

float8 **ST\_SetRotation**(raster rast, float8 rotation);

**Description**

Uniformly rotate the raster. Rotation is in radian. Refer to [World File](#) for more details.

**Examples**

```
SELECT
 ST_ScaleX(rast1), ST_ScaleY(rast1), ST_SkewX(rast1), ST_SkewY(rast1),
 ST_ScaleX(rast2), ST_ScaleY(rast2), ST_SkewX(rast2), ST_SkewY(rast2)
FROM (
 SELECT ST_SetRotation(rast, 15) AS rast1, rast as rast2 FROM dummy_rast
```

```
) AS foo;
 st_scalex | st_scaley | st_skewx | st_skewy | ↔
-----+-----+-----+-----+-----
-1.51937582571764 | -2.27906373857646 | 1.95086352047135 | 1.30057568031423 | ↔
 2 | 3 | 0 | 0
-0.0379843956429411 | -0.0379843956429411 | 0.0325143920078558 | 0.0325143920078558 | ↔
 0.05 | -0.05 | 0 | 0
```

**See Also**

[ST\\_Rotation](#), [ST\\_ScaleX](#), [ST\\_ScaleY](#), [ST\\_SkewX](#), [ST\\_SkewY](#)

**9.7.3 ST\_SetScale**

ST\_SetScale — Sets the X and Y size of pixels in units of coordinate reference system. Number units/pixel width/height.

**Synopsis**

```
raster ST_SetScale(raster rast, float8 xy);
raster ST_SetScale(raster rast, float8 x, float8 y);
```

**Description**

Sets the X and Y size of pixels in units of coordinate reference system. Number units/pixel width/height. If only one unit passed in, assumed X and Y are the same number.

---

 **Note** ST\_SetScale is different from [ST\\_Rescale](#) in that ST\_SetScale do not resample the raster to match the raster extent. It only changes the metadata (or georeference) of the raster to correct an originally mis-specified scaling. ST\_Rescale results in a raster having different width and height computed to fit the geographic extent of the input raster. ST\_SetScale do not modify the width, nor the height of the raster.

---

Changed: 2.0.0 In WKTRaster versions this was called ST\_SetPixelSize. This was changed in 2.0.0.

**Examples**

```
UPDATE dummy_rast
 SET rast = ST_SetScale(rast, 1.5)
WHERE rid = 2;

SELECT ST_ScaleX(rast) As pixx, ST_ScaleY(rast) As pixy, Box3D(rast) As newbox
FROM dummy_rast
WHERE rid = 2;

pixx | pixy | newbox
-----+-----+-----
1.5 | 1.5 | BOX(3427927.75 5793244 0, 3427935.25 5793251.5 0)
```

```
UPDATE dummy_rast
 SET rast = ST_SetScale(rast, 1.5, 0.55)
WHERE rid = 2;

SELECT ST_ScaleX(rast) As pixx, ST_ScaleY(rast) As pixy, Box3D(rast) As newbox
FROM dummy_rast
WHERE rid = 2;
```

pixx	pixy	newbox
1.5	0.55	BOX(3427927.75 5793244 0,3427935.25 5793247 0)

## See Also

## 9.7.4 ST\_SetSkew

`ST_SetSkew` — Sets the georeference X and Y skew (or rotation parameter). If only one is passed in, sets X and Y to the same value.

### Synopsis

```
raster ST_SetSkew(raster rast, float8 skewxy);
raster ST_SetSkew(raster rast, float8 skewx, float8 skewy);
```

### Description

Sets the georeference X and Y skew (or rotation parameter). If only one is passed in, sets X and Y to the same value. Refer to [World File](#) for more details.

### Examples

```
-- Example 1
UPDATE dummy_rast SET rast = ST_SetSkew(rast,1,2) WHERE rid = 1;
SELECT rid, ST_SkewX(rast) As skewx, ST_SkewY(rast) As skewy,
 ST_GeoReference(rast) as georef
FROM dummy_rast WHERE rid = 1;
```

rid	skewx	skewy	georef
1	1	2	2.0000000000 : 2.0000000000 : 1.0000000000 : 3.0000000000 : 0.5000000000 : 0.5000000000

```
-- Example 2 set both to same number:
UPDATE dummy_rast SET rast = ST_SetSkew(rast,0) WHERE rid = 1;
SELECT rid, ST_SkewX(rast) As skewx, ST_SkewY(rast) As skewy,
 ST_GeoReference(rast) as georef
FROM dummy_rast WHERE rid = 1;
```

rid	skewx	skewy	georef
1	0	0	2.0000000000 : 0.0000000000 : 0.0000000000 : 3.0000000000 : 0.5000000000 : 0.5000000000

**See Also**

[ST\\_GeoReference](#), [ST\\_SetGeoReference](#), [ST\\_SkewX](#), [ST\\_SkewY](#)

**9.7.5 ST\_SetSRID**

`ST_SetSRID` — Sets the SRID of a raster to a particular integer srid defined in the `spatial_ref_sys` table.

**Synopsis**

```
raster ST_SetSRID(raster rast, integer srid);
```

**Description**

Sets the SRID on a raster to a particular integer value.

**Note**

This function does not transform the raster in any way - it simply sets meta data defining the spatial ref of the coordinate reference system that it's currently in. Useful for transformations later.

**See Also**

Section [4.3.1](#), [ST\\_SRID](#)

**9.7.6 ST\_SetUpperLeft**

`ST_SetUpperLeft` — Sets the value of the upper left corner of the pixel to projected X and Y coordinates.

**Synopsis**

```
raster ST_SetUpperLeft(raster rast, double precision x, double precision y);
```

**Description**

Set the value of the upper left corner of raster to the projected X coordinates

## Examples

```
SELECT ST_SetUpperLeft(rast,-71.01,42.37)
FROM dummy_rast
WHERE rid = 2;
```

## See Also

[ST\\_UpperLeftX](#), [ST\\_UpperLeftY](#)

## 9.7.7 ST\_Resample

**ST\_Resample** — Resample a raster using a specified resampling algorithm, new dimensions, an arbitrary grid corner and a set of raster georeferencing attributes defined or borrowed from another raster.

### Synopsis

```
raster ST_Resample(raster rast, integer width, integer height, double precision gridx=NULL, double precision gridy=NULL,
double precision skewx=0, double precision skewy=0, text algorithm=NearestNeighbour, double precision maxerr=0.125);
raster ST_Resample(raster rast, double precision scalex=0, double precision scaley=0, double precision gridx=NULL, double
precision gridy=NULL, double precision skewx=0, double precision skewy=0, text algorithm=NearestNeighbor, double preci-
sion maxerr=0.125);
raster ST_Resample(raster rast, raster ref, text algorithm=NearestNeighbour, double precision maxerr=0.125, boolean usescale=true);
raster ST_Resample(raster rast, raster ref, boolean usescale, text algorithm=NearestNeighbour, double precision maxerr=0.125);
```

### Description

Resample a raster using a specified resampling algorithm, new dimensions (width & height), a grid corner (gridx & gridy) and a set of raster georeferencing attributes (scalex, scaley, skewx & skewy) defined or borrowed from another raster. If using a reference raster, the two rasters must have the same SRID.

New pixel values are computed using the NearestNeighbor (English or American spelling), Bilinear, Cubic, CubicSpline or Lanczos resampling algorithm. Default is NearestNeighbor which is the fastest but produce the worst interpolation.

A maxerror percent of 0.125 is used if no `maxerr` is specified.

#### Note

Refer to: [GDAL Warp resampling methods](#) for more details.

Availability: 2.0.0 Requires GDAL 1.6.1+

Changed: 2.1.0 Parameter `srid` removed. Variants with a reference raster no longer applies the reference raster's SRID. Use `ST_Transform()` to reproject raster. Works on rasters with no SRID.

## Examples

```
SELECT
 ST_Width(orig) AS orig_width,
 ST_Width(reduce_100) AS new_width
FROM (
 SELECT
 rast AS orig,
```

```

 ST_Resample(rast,100,100) AS reduce_100
FROM aerials.boston
WHERE ST_Intersects(rast,
 ST_Transform(
 ST_MakeEnvelope(-71.128, 42.2392,-71.1277, 42.2397, 4326),26986)
)
LIMIT 1
) AS foo;

orig_width | new_width
-----+-----
 200 | 100

```

**See Also**

[ST\\_Rescale](#), [ST\\_Resize](#), [ST\\_Transform](#)

**9.7.8 ST\_Rescale**

**ST\_Rescale** — Resample a raster by adjusting only its scale (or pixel size). New pixel values are computed using the NearestNeighbor (english or american spelling), Bilinear, Cubic, CubicSpline or Lanczos resampling algorithm. Default is NearestNeighbor.

**Synopsis**

```

raster ST_Rescale(raster rast, double precision scalexy, text algorithm=NearestNeighbour, double precision maxerr=0.125);
raster ST_Rescale(raster rast, double precision scalex, double precision scaley, text algorithm=NearestNeighbour, double precision maxerr=0.125);

```

**Description**

Resample a raster by adjusting only its scale (or pixel size). New pixel values are computed using the NearestNeighbor (english or american spelling), Bilinear, Cubic, CubicSpline or Lanczos resampling algorithm. The default is NearestNeighbor which is the fastest but results in the worst interpolation.

`scalex` and `scaley` define the new pixel size. `scaley` must often be negative to get well oriented raster.

When the new `scalex` or `scaley` is not a divisor of the raster width or height, the extent of the resulting raster is expanded to encompass the extent of the provided raster. If you want to be sure to retain exact input extent see [ST\\_Resize](#)

A `maxerror` percent of 0.125 is used if no `maxerr` is specified.

**Note**

Refer to: [GDAL Warp resampling methods](#) for more details.

**Note**

**ST\_Rescale** is different from **ST\_SetScale** in that **ST\_SetScale** do not resample the raster to match the raster extent. **ST\_SetScale** only changes the metadata (or georeference) of the raster to correct an originally mis-specified scaling. **ST\_Rescale** results in a raster having different width and height computed to fit the geographic extent of the input raster. **ST\_SetScale** do not modify the width, nor the height of the raster.

Availability: 2.0.0 Requires GDAL 1.6.1+

Changed: 2.1.0 Works on rasters with no SRID

## Examples

A simple example rescaling a raster from a pixel size of 0.001 degree to a pixel size of 0.0015 degree.

```
-- the original raster pixel size
SELECT ST_PixelWidth(ST_AddBand(ST_MakeEmptyRaster(100, 100, 0, 0, 0.001, -0.001, 0, 0, ↵
 4269), '8BUI'::text, 1, 0)) width

width

0.001

-- the rescaled raster raster pixel size
SELECT ST_PixelWidth(ST_Rescale(ST_AddBand(ST_MakeEmptyRaster(100, 100, 0, 0, 0.001, ↵
 -0.001, 0, 0, 4269), '8BUI'::text, 1, 0), 0.0015)) width

width

0.0015
```

## See Also

### 9.7.9 ST\_Reskew

**ST\_Reskew** — Resample a raster by adjusting only its skew (or rotation parameters). New pixel values are computed using the NearestNeighbor (english or american spelling), Bilinear, Cubic, CubicSpline or Lanczos resampling algorithm. Default is NearestNeighbor.

#### Synopsis

```
raster ST_Reskew(raster rast, double precision skewxy, text algorithm=NearestNeighbour, double precision maxerr=0.125);
raster ST_Reskew(raster rast, double precision skewx, double precision skewy, text algorithm=NearestNeighbour, double precision maxerr=0.125);
```

#### Description

Resample a raster by adjusting only its skew (or rotation parameters). New pixel values are computed using the NearestNeighbor (english or american spelling), Bilinear, Cubic, CubicSpline or Lanczos resampling algorithm. The default is NearestNeighbor which is the fastest but results in the worst interpolation.

`skewx` and `skewy` define the new skew.

The extent of the new raster will encompass the extent of the provided raster.

A `maxerror` percent of 0.125 if no `maxerr` is specified.

#### Note

Refer to: [GDAL Warp resampling methods](#) for more details.

**Note**

ST\_Reskew is different from [ST\\_SetSkew](#) in that ST\_SetSkew do not resample the raster to match the raster extent. ST\_SetSkew only changes the metadata (or georeference) of the raster to correct an originally mis-specified skew. ST\_Reskew results in a raster having different width and height computed to fit the geographic extent of the input raster. ST\_SetSkew do not modify the width, nor the height of the raster.

Availability: 2.0.0 Requires GDAL 1.6.1+

Changed: 2.1.0 Works on rasters with no SRID

**Examples**

A simple example reskewing a raster from a skew of 0.0 to a skew of 0.0015.

```
-- the original raster non-rotated
SELECT ST_Rotation(ST_AddBand(ST_MakeEmptyRaster(100, 100, 0, 0, 0.001, -0.001, 0, 0, 4269) ←
, '8BUI'::text, 1, 0));

-- result
0

-- the reskewed raster raster rotation
SELECT ST_Rotation(ST_Reskew(ST_AddBand(ST_MakeEmptyRaster(100, 100, 0, 0, 0.001, -0.001, ←
0, 0, 4269), '8BUI'::text, 1, 0), 0.0015));

-- result
-0.982793723247329
```

**See Also**

[ST\\_Resample](#), [ST\\_Rescale](#), [ST\\_SetSkew](#), [ST\\_SetRotation](#), [ST\\_SkewX](#), [ST\\_SkewY](#), [ST\\_Transform](#)

**9.7.10 ST\_SnapToGrid**

ST\_SnapToGrid — Resample a raster by snapping it to a grid. New pixel values are computed using the NearestNeighbor (english or american spelling), Bilinear, Cubic, CubicSpline or Lanczos resampling algorithm. Default is NearestNeighbor.

**Synopsis**

```
raster ST_SnapToGrid(raster rast, double precision gridx, double precision gridy, text algorithm=NearestNeighbour, double
precision maxerr=0.125, double precision scalex=DEFAULT 0, double precision scaley=DEFAULT 0);
raster ST_SnapToGrid(raster rast, double precision gridx, double precision gridy, double precision scalex, double precision
scaley, text algorithm=NearestNeighbour, double precision maxerr=0.125);
raster ST_SnapToGrid(raster rast, double precision gridx, double precision gridy, double precision scalexy, text algorithm=NearestNeig
double precision maxerr=0.125);
```

**Description**

Resample a raster by snapping it to a grid defined by an arbitrary pixel corner (gridx & gridy) and optionally a pixel size (scalex & scaley). New pixel values are computed using the NearestNeighbor (english or american spelling), Bilinear, Cubic, CubicSpline or Lanczos resampling algorithm. The default is NearestNeighbor which is the fastest but results in the worst interpolation.

gridx and gridy define any arbitrary pixel corner of the new grid. This is not necessarily the upper left corner of the new raster and it does not have to be inside or on the edge of the new raster extent.

You can optional define the pixel size of the new grid with `scalex` and `scaley`.

The extent of the new raster will encompass the extent of the provided raster.

A `maxerror` percent of 0.125 if no `maxerr` is specified.

**Note**

Refer to: [GDAL Warp resampling methods](#) for more details.

**Note**

Use [ST\\_Resample](#) if you need more control over the grid parameters.

Availability: 2.0.0 Requires GDAL 1.6.1+

Changed: 2.1.0 Works on rasters with no SRID

## Examples

A simple example snapping a raster to a slightly different grid.

```
-- the original raster upper left X
SELECT ST_UpperLeftX(ST_AddBand(ST_MakeEmptyRaster(10, 10, 0, 0, 0.001, -0.001, 0, 0, 4269) ←
, '8BUI'::text, 1, 0));
-- result
0

-- the upper left of raster after snapping
SELECT ST_UpperLeftX(ST_SnapToGrid(ST_AddBand(ST_MakeEmptyRaster(10, 10, 0, 0, 0.001, ←
-0.001, 0, 0, 4269), '8BUI'::text, 1, 0), 0.0002, 0.0002));

--result
-0.0008
```

## 9.7.11 ST\_Resize

`ST_Resize` — Resize a raster to a new width/height

### Synopsis

```
raster ST_Resize(raster rast, integer width, integer height, text algorithm=NearestNeighbor, double precision maxerr=0.125);
raster ST_Resize(raster rast, double precision percentwidth, double precision percentheight, text algorithm=NearestNeighbor,
double precision maxerr=0.125);
raster ST_Resize(raster rast, text width, text height, text algorithm=NearestNeighbor, double precision maxerr=0.125);
```

**See Also**

[ST\\_Resample](#), [ST\\_Rescale](#), [ST\\_Reskew](#), [ST\\_SnapToGrid](#)

**9.7.12 ST\_Transform**

**ST\_Transform** — Reprojects a raster in a known spatial reference system to another known spatial reference system using specified resampling algorithm. Options are NearestNeighbor, Bilinear, Cubic, CubicSpline, Lanczos defaulting to NearestNeighbor.

**Synopsis**

```
raster ST_Transform(raster rast, integer srid, text algorithm=NearestNeighbor, double precision maxerr=0.125, double precision scalex, double precision scaley);
```

```
raster ST_Transform(raster rast, integer srid, double precision scalex, double precision scaley, text algorithm=NearestNeighbor, double precision maxerr=0.125);
```

```
raster ST_Transform(raster rast, raster alignto, text algorithm=NearestNeighbor, double precision maxerr=0.125);
```

**Description**

Reprojects a raster in a known spatial reference system to another known spatial reference system using specified pixel warping algorithm. Uses 'NearestNeighbor' if no algorithm is specified and maxerror percent of 0.125 if no maxerr is specified.

Algorithm options are: 'NearestNeighbor', 'Bilinear', 'Cubic', 'CubicSpline', and 'Lanczos'. Refer to: [GDAL Warp resampling methods](#) for more details.

**ST\_Transform** is often confused with **ST\_SetSRID()**. **ST\_Transform** actually changes the coordinates of a raster (and resamples the pixel values) from one spatial reference system to another, while **ST\_SetSRID()** simply changes the SRID identifier of the raster.

Unlike the other variants, Variant 3 requires a reference raster as `alignto`. The transformed raster will be transformed to the spatial reference system (SRID) of the reference raster and be aligned (`ST_SameAlignment = TRUE`) to the reference raster.

**Note**

If you find your transformation support is not working right, you may need to set the environment variable `PROJSO` to the `.so` or `.dll` projection library your PostGIS is using. This just needs to have the name of the file. So for example on windows, you would in Control Panel -> System -> Environment Variables add a system variable called `PROJSO` and set it to `libproj.dll` (if you are using proj 4.6.1). You'll have to restart your PostgreSQL service/daemon after this change.

Availability: 2.0.0 Requires GDAL 1.6.1+

Enhanced: 2.1.0 Addition of `ST_Transform(rast, alignto)` variant

**Examples**

```
SELECT ST_Width(mass_stm) As w_before, ST_Width(wgs_84) As w_after,
 ST_Height(mass_stm) As h_before, ST_Height(wgs_84) As h_after
FROM
 (SELECT rast As mass_stm, ST_Transform(rast,4326) As wgs_84
 , ST_Transform(rast,4326, 'Bilinear') AS wgs_84_bilin
 FROM aerials.o_2_boston
 WHERE ST_Intersects(rast,
 ST_Transform(ST_MakeEnvelope(-71.128, 42.2392,-71.1277, 42.2397, 4326),26986))
 LIMIT 1) As foo;
```

w_before	w_after	h_before	h_after
200	228	200	170

**Examples: Variant 3**

The following shows the difference between using ST\_Transform(raster, srid) and ST\_Transform(raster, alignto)

```

WITH foo AS (
 SELECT 0 AS rid, ST_AddBand(ST_MakeEmptyRaster(2, 2, -500000, 600000, 100, -100, 0, 0, ←
 2163), 1, '16BUI', 1, 0) AS rast UNION ALL
 SELECT 1, ST_AddBand(ST_MakeEmptyRaster(2, 2, -499800, 600000, 100, -100, 0, 0, 2163), 1, ←
 '16BUI', 2, 0) AS rast UNION ALL
 SELECT 2, ST_AddBand(ST_MakeEmptyRaster(2, 2, -499600, 600000, 100, -100, 0, 0, 2163), 1, ←
 '16BUI', 3, 0) AS rast UNION ALL

 SELECT 3, ST_AddBand(ST_MakeEmptyRaster(2, 2, -500000, 599800, 100, -100, 0, 0, 2163), 1, ←
 '16BUI', 10, 0) AS rast UNION ALL
 SELECT 4, ST_AddBand(ST_MakeEmptyRaster(2, 2, -499800, 599800, 100, -100, 0, 0, 2163), 1, ←

## 9.8 Raster Band Editors

### 9.8.1 ST\_SetBandNoDataValue

`ST_SetBandNoDataValue` — Sets the value for the given band that represents no data. Band 1 is assumed if no band is specified. To mark a band as having no nodata value, set the nodata value = NULL.

**Synopsis**

```

raster ST_SetBandNoDataValue(raster rast, double precision nodatavalue);
raster ST_SetBandNoDataValue(raster rast, integer band, double precision nodatavalue, boolean forcechecking=false);

```

**Description**

Sets the value that represents no data for the band. Band 1 is assumed if not specified. This will affect results from [ST\\_Polygon](#), [ST\\_DumpAsPolygons](#), and the `ST_PixelAs...()` functions.

**Examples**

```

-- change just first band no data value
UPDATE dummy_rast
 SET rast = ST_SetBandNoDataValue(rast,1, 254)
WHERE rid = 2;

-- change no data band value of bands 1,2,3
UPDATE dummy_rast
 SET rast =
 ST_SetBandNoDataValue(
 ST_SetBandNoDataValue(
 ST_SetBandNoDataValue(
 rast,1, 254)
 ,2,99),
 3,108)
 WHERE rid = 2;

-- wipe out the nodata value this will ensure all pixels are considered for all processing ←
functions

```

```
UPDATE dummy_rast
 SET rast = ST_SetBandNoDataValue(rast,1, NULL)
WHERE rid = 2;
```

### See Also

[ST\\_BandNoDataValue](#), [ST\\_NumBands](#)

## 9.8.2 ST\_SetBandIsNoData

`ST_SetBandIsNoData` — Sets the `isnodata` flag of the band to `TRUE`.

### Synopsis

raster `ST_SetBandIsNoData`(raster rast, integer band=1);

### Description

Sets the `isnodata` flag for the band to true. Band 1 is assumed if not specified. This function should be called only when the flag is considered dirty. That is, when the result calling [ST\\_BandIsNoData](#) is different using `TRUE` as last argument and without using it

Availability: 2.0.0

### Examples

```
-- Create dummy table with one raster column
create table dummy_rast (rid integer, rast raster);

-- Add raster with two bands, one pixel/band. In the first band, nodatavalue = pixel value ←
 = 3.
-- In the second band, nodatavalue = 13, pixel value = 4
insert into dummy_rast values(1,

## 9.9 Raster Band Statistics and Analytics

### 9.9.1 ST\_Count

**ST\_Count** — Returns the number of pixels in a given band of a raster or raster coverage. If no band is specified defaults to band 1. If `exclude_nodata_value` is set to true, will only count pixels that are not equal to the nodata value.

**Synopsis**

```

bigint ST_Count(raster rast, integer nband=1, boolean exclude_nodata_value=true);
bigint ST_Count(raster rast, boolean exclude_nodata_value);
bigint ST_Count(text rastertable, text rastercolumn, integer nband=1, boolean exclude_nodata_value=true);
bigint ST_Count(text rastertable, text rastercolumn, boolean exclude_nodata_value);

```

**Description**

Returns the number of pixels in a given band of a raster or raster coverage. If no band is specified `nband` defaults to 1.

**Note**

If `exclude_nodata_value` is set to true, will only count pixels with value not equal to the `nodata` value of the raster. Set `exclude_nodata_value` to false to get count all pixels

Availability: 2.0.0

**Warning**

The `ST_Count(rastertable, rastercolumn, ...)` variants are deprecated as of 2.2.0. Use `ST_CountAgg` instead.

**Examples**

```
--example will count all pixels not 249 and one will count all pixels. --
SELECT rid, ST_Count(ST_SetBandNoDataValue(rast,249)) As exclude_nodata,
 ST_Count(ST_SetBandNoDataValue(rast,249),false) As include_nodata
FROM dummy_rast WHERE rid=2;
```

```
rid | exclude_nodata | include_nodata
-----+-----+-----
 2 | | 23 | 25
```

**See Also**

[ST\\_CountAgg](#), [ST\\_SummaryStats](#), [ST\\_SetBandNoDataValue](#)

**9.9.2 ST\_CountAgg**

`ST_CountAgg` — Aggregate. Returns the number of pixels in a given band of a set of rasters. If no band is specified defaults to band 1. If `exclude_nodata_value` is set to true, will only count pixels that are not equal to the `NODATA` value.

**Synopsis**

```
bigint ST_CountAgg(raster rast, integer nband, boolean exclude_nodata_value, double precision sample_percent);
bigint ST_CountAgg(raster rast, integer nband, boolean exclude_nodata_value);
bigint ST_CountAgg(raster rast, boolean exclude_nodata_value);
```

**Description**

Returns the number of pixels in a given band of a set of rasters. If no band is specified `nband` defaults to 1.

If `exclude_nodata_value` is set to true, will only count pixels with value not equal to the `NODATA` value of the raster. Set `exclude_nodata_value` to false to get count all pixels

By default will sample all pixels. To get faster response, set `sample_percent` to value between zero (0) and one (1)

Availability: 2.2.0

## Examples

```

WITH foo AS (
 SELECT
 rast.rast
 FROM (
 SELECT ST_SetValue(
 ST_SetValue(
 ST_SetValue(
 ST_AddBand(
 ST_MakeEmptyRaster(10, 10, 10, 10, 2, 2, 0, 0,0)
 , 1, '64BF', 0, 0
)
 , 1, 1, 1, -10
)
 , 1, 5, 4, 0
) AS rast
) AS rast
 FULL JOIN (
 SELECT generate_series(1, 10) AS id
) AS id
 ON 1 = 1
)
SELECT
 ST_CountAgg(rast, 1, TRUE)
FROM foo;

 st_countagg

 20
(1 row)

```

## See Also

[ST\\_Count](#), [ST\\_SummaryStats](#), [ST\\_SetBandNoDataValue](#)

### 9.9.3 ST\_Histogram

**ST\_Histogram** — Returns a set of record summarizing a raster or raster coverage data distribution separate bin ranges. Number of bins are autocomputed if not specified.

#### Synopsis

```

SETOF record ST_Histogram(raster rast, integer nband=1, boolean exclude_nodata_value=true, integer bins=autocomputed,
double precision[] width=NULL, boolean right=false);
SETOF record ST_Histogram(raster rast, integer nband, integer bins, double precision[] width=NULL, boolean right=false);
SETOF record ST_Histogram(raster rast, integer nband, boolean exclude_nodata_value, integer bins, boolean right);
SETOF record ST_Histogram(raster rast, integer nband, integer bins, boolean right);
SETOF record ST_Histogram(text rastertable, text rastercolumn, integer nband, integer bins, boolean right);
SETOF record ST_Histogram(text rastertable, text rastercolumn, integer nband, boolean exclude_nodata_value, integer bins,
boolean right);
SETOF record ST_Histogram(text rastertable, text rastercolumn, integer nband=1, boolean exclude_nodata_value=true, integer
bins=autocomputed, double precision[] width=NULL, boolean right=false);
SETOF record ST_Histogram(text rastertable, text rastercolumn, integer nband=1, integer bins, double precision[] width=NULL,
boolean right=false);

```

**Description**

Returns set of records consisting of min, max, count, percent for a given raster band for each bin. If no band is specified nband defaults to 1.

**Note**

By default only considers pixel values not equal to the `nodata` value . Set `exclude_nodata_value` to `false` to get count all pixels.

**width** *double precision[]* width: an array indicating the width of each category/bin. If the number of bins is greater than the number of widths, the widths are repeated.

Example: 9 bins, widths are [a, b, c] will have the output be [a, b, c, a, b, c, a, b, c]

**bins** *integer* Number of breakouts -- this is the number of records you'll get back from the function if specified. If not specified then the number of breakouts is autocomputed.

**right** *boolean* compute the histogram from the right rather than from the left (default). This changes the criteria for evaluating a value x from [a, b) to (a, b]

Availability: 2.0.0

**Example: Single raster tile - compute histograms for bands 1, 2, 3 and autocompute bins**

```
SELECT band, (stats).*
FROM (SELECT rid, band, ST_Histogram(rast, band) As stats
 FROM dummy_rast CROSS JOIN generate_series(1,3) As band
 WHERE rid=2) As foo;
```

band	min	max	count	percent
1	249	250	2	0.08
1	250	251	2	0.08
1	251	252	1	0.04
1	252	253	2	0.08
1	253	254	18	0.72
2	78	113.2	11	0.44
2	113.2	148.4	4	0.16
2	148.4	183.6	4	0.16
2	183.6	218.8	1	0.04
2	218.8	254	5	0.2
3	62	100.4	11	0.44
3	100.4	138.8	5	0.2
3	138.8	177.2	4	0.16
3	177.2	215.6	1	0.04
3	215.6	254	4	0.16

**Example: Just band 2 but for 6 bins**

```
SELECT (stats).*
FROM (SELECT rid, ST_Histogram(rast, 2,6) As stats
 FROM dummy_rast
 WHERE rid=2) As foo;
```

min	max	count	percent
78	113.2	11	0.44
113.2	148.4	4	0.16
148.4	183.6	4	0.16
183.6	218.8	1	0.04
218.8	254	5	0.2

```

## 9.9.4 ST\_Quantile

**ST\_Quantile** — Compute quantiles for a raster or raster table coverage in the context of the sample or population. Thus, a value could be examined to be at the raster's 25%, 50%, 75% percentile.

### Synopsis

```

SETOF record ST_Quantile(raster rast, integer nband=1, boolean exclude_nodata_value=true, double precision[] quantiles=NULL);
SETOF record ST_Quantile(raster rast, double precision[] quantiles);
SETOF record ST_Quantile(raster rast, integer nband, double precision[] quantiles);
double precision ST_Quantile(raster rast, double precision quantile);
double precision ST_Quantile(raster rast, boolean exclude_nodata_value, double precision quantile=NULL);
double precision ST_Quantile(raster rast, integer nband, double precision quantile);
double precision ST_Quantile(raster rast, integer nband, boolean exclude_nodata_value, double precision quantile);
double precision ST_Quantile(raster rast, integer nband, double precision quantile);
SETOF record ST_Quantile(text rastertable, text rastercolumn, integer nband=1, boolean exclude_nodata_value=true, double
precision[] quantiles=NULL);
SETOF record ST_Quantile(text rastertable, text rastercolumn, integer nband, double precision[] quantiles);

```

### Description

Compute quantiles for a raster or raster table coverage in the context of the sample or population. Thus, a value could be examined to be at the raster's 25%, 50%, 75% percentile.

#### Note

If `exclude_nodata_value` is set to false, will also count pixels with no data.

Availability: 2.0.0

## Examples

```
UPDATE dummy_rast SET rast = ST_SetBandNoDataValue(rast,249) WHERE rid=2;
--Example will consider only pixels of band 1 that are not 249 and in named quantiles --
```

```
SELECT (pvq).*

**9.9.5 ST\_SummaryStats**

`ST_SummaryStats` — Returns summarystats consisting of count, sum, mean, stddev, min, max for a given raster band of a raster or raster coverage. Band 1 is assumed is no band is specified.

**Synopsis**

```
summarystats ST_SummaryStats(raster rast, boolean exclude_nodata_value);
summarystats ST_SummaryStats(raster rast, integer nband, boolean exclude_nodata_value);
summarystats ST_SummaryStats(text rastertable, text rastercolumn, boolean exclude_nodata_value);
summarystats ST_SummaryStats(text rastertable, text rastercolumn, integer nband=1, boolean exclude_nodata_value=true);
```

**Description**

Returns **summarystats** consisting of count, sum, mean, stddev, min, max for a given raster band of a raster or raster coverage. If no band is specified `nband` defaults to 1.

**Note**

By default only considers pixel values not equal to the `nodata` value. Set `exclude_nodata_value` to `false` to get count of all pixels.

**Note**

By default will sample all pixels. To get faster response, set `sample_percent` to lower than 1

Availability: 2.0.0

**Warning**

The `ST_SummaryStats(rastertable, rastercolumn, ...)` variants are deprecated as of 2.2.0. Use [ST\\_SummaryStatsAgg](#) instead.

**Example: Single raster tile**

```
SELECT rid, band, (stats).*
FROM (SELECT rid, band, ST_SummaryStats(rast, band) As stats
 FROM dummy_rast CROSS JOIN generate_series(1,3) As band
 WHERE rid=2) As foo;
```

rid	band	count	sum	mean	stddev	min	max
2	1	23	5821	253.086957	1.248061	250	254
2	2	25	3682	147.28	59.862188	78	254
2	3	25	3290	131.6	61.647384	62	254

**Example: Summarize pixels that intersect buildings of interest**

This example took 574ms on PostGIS windows 64-bit with all of Boston Buildings and aerial Tiles (tiles each 150x150 pixels ~ 134,000 tiles), ~102,000 building records

```
WITH
-- our features of interest
 feat AS (SELECT gid As building_id, geom_26986 As geom FROM buildings AS b
 WHERE gid IN(100, 103,150)
),
-- clip band 2 of raster tiles to boundaries of builds
-- then get stats for these clipped regions
 b_stats AS
 (SELECT building_id, (stats).*
FROM (SELECT building_id, ST_SummaryStats(ST_Clip(rast,2,geom)) As stats
 FROM aerials.boston
 INNER JOIN feat
 ON ST_Intersects(feats.geom,rast)
) As foo
)
-- finally summarize stats
SELECT building_id, SUM(count) As num_pixels
 , MIN(min) As min_pval
 , MAX(max) As max_pval
 , SUM(mean*count)/SUM(count) As avg_pval
FROM b_stats
WHERE count > 0
GROUP BY building_id
ORDER BY building_id;
```

building_id	num_pixels	min_pval	max_pval	avg_pval
100	1090	1	255	61.0697247706422
103	655	7	182	70.5038167938931
150	895	2	252	185.642458100559

**Example: Raster coverage**

```
-- stats for each band --
SELECT band, (stats).*
FROM (SELECT band, ST_SummaryStats('o_4_boston','rast', band) As stats
 FROM generate_series(1,3) As band) As foo;
```

band	count	sum	mean	stddev	min	max
1	8450000	725799	82.7064349112426	45.6800222638537	0	255

**See Also**

[summarystats](#), [ST\\_SummaryStatsAgg](#), [ST\\_Count](#), [ST\\_Clip](#)

**9.9.6 ST\_SummaryStatsAgg**

`ST_SummaryStatsAgg` — Aggregate. Returns `summarystats` consisting of count, sum, mean, stddev, min, max for a given raster band of a set of raster. Band 1 is assumed is no band is specified.

**Synopsis**

```
summarystats ST_SummaryStatsAgg(raster rast, integer nband, boolean exclude_nodata_value, double precision sample_percent);
summarystats ST_SummaryStatsAgg(raster rast, boolean exclude_nodata_value, double precision sample_percent);
summarystats ST_SummaryStatsAgg(raster rast, integer nband, boolean exclude_nodata_value);
```

**Description**

Returns `summarystats` consisting of count, sum, mean, stddev, min, max for a given raster band of a raster or raster coverage. If no band is specified `nband` defaults to 1.

**Note**

By default only considers pixel values not equal to the `NODATA` value. Set `exclude_nodata_value` to `False` to get count of all pixels.

**Note**

By default will sample all pixels. To get faster response, set `sample_percent` to value between 0 and 1

Availability: 2.2.0

**Examples**

```
WITH foo AS (
 SELECT
 rast.rast
 FROM (
 SELECT ST_SetValue(
 ST_SetValue(
 ST_SetValue(
 ST_AddBand(
 ST_MakeEmptyRaster(10, 10, 10, 10, 2, 2, 0, 0,0)
 , 1, '64BF', 0, 0
)
 , 1, 1, 1, -10
)
 , 1, 5, 4, 0

## 9.9.7 ST\_ValueCount

**ST\_ValueCount** — Returns a set of records containing a pixel band value and count of the number of pixels in a given band of a raster (or a raster coverage) that have a given set of values. If no band is specified defaults to band 1. By default nodata value pixels are not counted. and all other values in the pixel are output and pixel band values are rounded to the nearest integer.

### Synopsis

```

SETOF record ST_ValueCount(raster rast, integer nband=1, boolean exclude_nodata_value=true, double precision[] searchvalues=NULL, double precision roundto=0, double precision OUT value, integer OUT count);
SETOF record ST_ValueCount(raster rast, integer nband, double precision[] searchvalues, double precision roundto=0, double precision OUT value, integer OUT count);
SETOF record ST_ValueCount(raster rast, double precision[] searchvalues, double precision roundto=0, double precision OUT value, integer OUT count);
bigint ST_ValueCount(raster rast, double precision searchvalue, double precision roundto=0);
bigint ST_ValueCount(raster rast, integer nband, boolean exclude_nodata_value, double precision searchvalue, double precision roundto=0);
bigint ST_ValueCount(raster rast, integer nband, double precision searchvalue, double precision roundto=0);
SETOF record ST_ValueCount(text rastertable, text rastercolumn, integer nband=1, boolean exclude_nodata_value=true, double precision[] searchvalues=NULL, double precision roundto=0, double precision OUT value, integer OUT count);
SETOF record ST_ValueCount(text rastertable, text rastercolumn, double precision[] searchvalues, double precision roundto=0, double precision OUT value, integer OUT count);
SETOF record ST_ValueCount(text rastertable, text rastercolumn, integer nband, double precision[] searchvalues, double precision roundto=0, double precision OUT value, integer OUT count);
bigint ST_ValueCount(text rastertable, text rastercolumn, integer nband, boolean exclude_nodata_value, double precision searchvalue, double precision roundto=0);
bigint ST_ValueCount(text rastertable, text rastercolumn, double precision searchvalue, double precision roundto=0);
bigint ST_ValueCount(text rastertable, text rastercolumn, integer nband, double precision searchvalue, double precision roundto=0);

```

## Description

Returns a set of records with columns `value` `count` which contain the pixel band value and count of pixels in the raster tile or raster coverage of selected band.

If no band is specified `nband` defaults to 1. If no `searchvalues` are specified, will return all pixel values found in the raster or raster coverage. If one `searchvalue` is given, will return an integer instead of records denoting the count of pixels having that pixel band value

### Note

If `exclude_nodata_value` is set to `false`, will also count pixels with no data.

Availability: 2.0.0

## Examples

```
UPDATE dummy_rast SET rast = ST_SetBandNoDataValue(rast,249) WHERE rid=2;
--Example will count only pixels of band 1 that are not 249. --

## 9.10 Raster Outputs

### 9.10.1 ST\_AsBinary

`ST_AsBinary` — Return the Well-Known Binary (WKB) representation of the raster.

**Synopsis**

```
bytea ST_AsBinary(raster rast, boolean outasin=FALSE);
```

**Description**

Returns the Binary representation of the raster. If `outasin` is TRUE, out-db bands are treated as in-db. Refer to raster/doc/RFC2-WellKnownBinaryFormat located in the PostGIS source folder for details of the representation.

This is useful in binary cursors to pull data out of the database without converting it to a string representation.

**Note**

By default, WKB output contains the external file path for out-db bands. If the client does not have access to the raster file underlying an out-db band, set `outasin` to TRUE.

Enhanced: 2.1.0 Addition of `outasin`

**Examples**

```
SELECT ST_AsBinary(rast) As rastbin FROM dummy_rast WHERE rid=1;
```

```
 rastbin

```

```
\001\000\000\000\000\000\000\000\000\000\000\000\000\000\000\000@000\000\000\000\000\000\000\010@000\000\000\000\000\000\000\000\000\000\000\340?\000\000\000\000\000\000\000\000\000\000\340?\000\012\000\000\000\012\000\024\000
```

**9.10.2 ST\_AsGDALRaster**

**ST\_AsGDALRaster** — Return the raster tile in the designated GDAL Raster format. Raster formats are one of those supported by your compiled library. Use `ST_GDALRasters()` to get a list of formats supported by your library.

**Synopsis**

```
bytea ST_AsGDALRaster(raster rast, text format, text[] options=NULL, integer srid=sameassource);
```

**Description**

Returns the raster tile in the designated format. Arguments are itemized below:

- `format` format to output. This is dependent on the drivers compiled in your libgdal library. Generally available are 'JPEG', 'GTiff', 'PNG'. Use [ST\\_GDALDrivers](#) to get a list of formats supported by your library.
- `options` text array of GDAL options. Valid options are dependent on the format. Refer to [GDAL Raster format options](#) for more details.
- `srs` The proj4text or srtext (from `spatial_ref_sys`) to embed in the image

Availability: 2.0.0 - requires GDAL >= 1.6.0.

## JPEG Output Examples

```
SELECT ST_AsGDALRaster(rast, 'JPEG') As rastjpg
FROM dummy_rast WHERE rid=1;

SELECT ST_AsGDALRaster(rast, 'JPEG', ARRAY['QUALITY=50']) As rastjpg
FROM dummy_rast WHERE rid=2;
```

## GTIFF Output Examples

```
SELECT ST_AsGDALRaster(rast, 'GTiff') As rastjpg
FROM dummy_rast WHERE rid=2;

-- Out GeoTiff with jpeg compression, 90% quality
SELECT ST_AsGDALRaster(rast, 'GTiff',
 ARRAY['COMPRESS=JPEG', 'JPEG_QUALITY=90'],
 4269) As rasttiff
FROM dummy_rast WHERE rid=2;
```

## See Also

Section 5.3, [ST\\_GDALDrivers](#), [ST\\_SRID](#)

### 9.10.3 ST\_AsJPEG

**ST\_AsJPEG** — Return the raster tile selected bands as a single Joint Photographic Exports Group (JPEG) image (byte array). If no band is specified and 1 or more than 3 bands, then only the first band is used. If only 3 bands then all 3 bands are used and mapped to RGB.

#### Synopsis

```
bytea ST_AsJPEG(raster rast, text[] options=NULL);
bytea ST_AsJPEG(raster rast, integer nband, integer quality);
bytea ST_AsJPEG(raster rast, integer nband, text[] options=NULL);
bytea ST_AsJPEG(raster rast, integer[] nbands, text[] options=NULL);
bytea ST_AsJPEG(raster rast, integer[] nbands, integer quality);
```

#### Description

Returns the selected bands of the raster as a single Joint Photographic Exports Group Image (JPEG). Use [ST\\_AsGDALRaster](#) if you need to export as less common raster types. If no band is specified and 1 or more than 3 bands, then only the first band is used. If 3 bands then all 3 bands are used. There are many variants of the function with many options. These are itemized below:

- `nband` is for single band exports.
- `nbands` is an array of bands to export (note that max is 3 for JPEG) and the order of the bands is RGB. e.g `ARRAY[3,2,1]` means map band 3 to Red, band 2 to green and band 1 to blue
- `quality` number from 0 to 100. The higher the number the crisper the image.
- `options` text Array of GDAL options as defined for JPEG (look at `create_options` for JPEG [ST\\_GDALDrivers](#)). For JPEG valid ones are `PROGRESSIVE ON` or `OFF` and `QUALITY` a range from 0 to 100 and default to 75. Refer to [GDAL Raster format options](#) for more details.

Availability: 2.0.0 - requires GDAL >= 1.6.0.

**Examples: Output**

```
-- output first 3 bands 75% quality
SELECT ST_AsJPEG(rast) As rastjpg
 FROM dummy_rast WHERE rid=2;

-- output only first band as 90% quality
SELECT ST_AsJPEG(rast,1,90) As rastjpg
 FROM dummy_rast WHERE rid=2;

-- output first 3 bands (but make band 2 Red, band 1 green, and band 3 blue, progressive ←
 and 90% quality
SELECT ST_AsJPEG(rast,ARRAY[2,1,3],ARRAY['QUALITY=90','PROGRESSIVE=ON']) As rastjpg
 FROM dummy_rast WHERE rid=2;
```

**See Also**

Section 5.3, [ST\\_GDALDrivers](#), [ST\\_AsGDALRaster](#), [ST\\_AsPNG](#), [ST\\_AsTIFF](#)

**9.10.4 ST\_AsPNG**

**ST\_AsPNG** — Return the raster tile selected bands as a single portable network graphics (PNG) image (byte array). If 1, 3, or 4 bands in raster and no bands are specified, then all bands are used. If more 2 or more than 4 bands and no bands specified, then only band 1 is used. Bands are mapped to RGB or RGBA space.

**Synopsis**

```
bytea ST_AsPNG(raster rast, text[] options=NULL);
bytea ST_AsPNG(raster rast, integer nband, integer compression);
bytea ST_AsPNG(raster rast, integer nband, text[] options=NULL);
bytea ST_AsPNG(raster rast, integer[] nbands, integer compression);
bytea ST_AsPNG(raster rast, integer[] nbands, text[] options=NULL);
```

**Description**

Returns the selected bands of the raster as a single Portable Network Graphics Image (PNG). Use [ST\\_AsGDALRaster](#) if you need to export as less common raster types. If no band is specified, then the first 3 bands are exported. There are many variants of the function with many options. If no `srid` is specified then then `srid` of the raster is used. These are itemized below:

- `nband` is for single band exports.
- `nbands` is an array of bands to export (note that max is 4 for PNG) and the order of the bands is RGBA. e.g `ARRAY[3,2,1]` means map band 3 to Red, band 2 to green and band 1 to blue
- `compression` number from 1 to 9. The higher the number the greater the compression.
- `options` text Array of GDAL options as defined for PNG (look at `create_options` for PNG of [ST\\_GDALDrivers](#)). For PNG valid one is only `ZLEVEL` (amount of time to spend on compression -- default 6) e.g. `ARRAY['ZLEVEL=9']`. `WORLDFILE` is not allowed since the function would have to output two outputs. Refer to [GDAL Raster format options](#) for more details.

Availability: 2.0.0 - requires GDAL >= 1.6.0.

## Examples

```
SELECT ST_AsPNG(rast) As rastpng
FROM dummy_rast WHERE rid=2;

-- export the first 3 bands and map band 3 to Red, band 1 to Green, band 2 to blue
SELECT ST_AsPNG(rast, ARRAY[3,1,2]) As rastpng
FROM dummy_rast WHERE rid=2;
```

## See Also

[ST\\_AsGDALRaster](#), [ST\\_ColorMap](#), [ST\\_GDALDrivers](#), [Section 5.3](#)

### 9.10.5 ST\_AsTIFF

**ST\_AsTIFF** — Return the raster selected bands as a single TIFF image (byte array). If no band is specified, then will try to use all bands.

#### Synopsis

```
bytea ST_AsTIFF(raster rast, text[] options="", integer srid=sameassource);
bytea ST_AsTIFF(raster rast, text compression="", integer srid=sameassource);
bytea ST_AsTIFF(raster rast, integer[] nbands, text compression="", integer srid=sameassource);
bytea ST_AsTIFF(raster rast, integer[] nbands, text[] options, integer srid=sameassource);
```

#### Description

Returns the selected bands of the raster as a single Tagged Image File Format (TIFF). If no band is specified, will try to use all bands. This is a wrapper around [ST\\_AsGDALRaster](#). Use [ST\\_AsGDALRaster](#) if you need to export as less common raster types. There are many variants of the function with many options. If no spatial reference SRS text is present, the spatial reference of the raster is used. These are itemized below:

- `nbands` is an array of bands to export (note that max is 3 for PNG) and the order of the bands is RGB. e.g `ARRAY[3,2,1]` means map band 3 to Red, band 2 to green and band 1 to blue
- `compression` Compression expression -- JPEG90 (or some other percent), LZW, JPEG, DEFLATE9.
- `options` text Array of GDAL create options as defined for GTiff (look at `create_options` for GTiff of [ST\\_GDALDrivers](#)). or refer to [GDAL Raster format options](#) for more details.
- `srid` srid of `spatial_ref_sys` of the raster. This is used to populate the georeference information

Availability: 2.0.0 - requires GDAL >= 1.6.0.

#### Examples: Use jpeg compression 90%

```
SELECT ST_AsTIFF(rast, 'JPEG90') As rasttiff
FROM dummy_rast WHERE rid=2;
```

## See Also

[ST\\_GDALDrivers](#), [ST\\_AsGDALRaster](#), [ST\\_SRID](#)

## 9.11 Raster Processing

### 9.11.1 Map Algebra

#### 9.11.1.1 ST\_Clip

**ST\_Clip** — Returns the raster clipped by the input geometry. If band number not is specified, all bands are processed. If `crop` is not specified or `TRUE`, the output raster is cropped.

#### Synopsis

```
raster ST_Clip(raster rast, integer[] nband, geometry geom, double precision[] nodataval=NULL, boolean crop=TRUE);
raster ST_Clip(raster rast, integer nband, geometry geom, double precision nodataval, boolean crop=TRUE);
raster ST_Clip(raster rast, integer nband, geometry geom, boolean crop);
raster ST_Clip(raster rast, geometry geom, double precision[] nodataval=NULL, boolean crop=TRUE);
raster ST_Clip(raster rast, geometry geom, double precision nodataval, boolean crop=TRUE);
raster ST_Clip(raster rast, geometry geom, boolean crop);
```

#### Description

Returns a raster that is clipped by the input geometry `geom`. If band index is not specified, all bands are processed.

Rasters resulting from `ST_Clip` must have a nodata value assigned for areas clipped, one for each band. If none are provided and the input raster do not have a nodata value defined, nodata values of the resulting raster are set to `ST_MinPossibleValue(ST_BandPixelType(rast, band))`. When the number of nodata value in the array is smaller than the number of band, the last one in the array is used for the remaining bands. If the number of nodata value is greater than the number of band, the extra nodata values are ignored. All variants accepting an array of nodata values also accept a single value which will be assigned to each band.

If `crop` is not specified, `true` is assumed meaning the output raster is cropped to the intersection of the `geom` and `rast` extents. If `crop` is set to `false`, the new raster gets the same extent as `rast`.

Availability: 2.0.0

Enhanced: 2.1.0 Rewritten in C

Examples here use Massachusetts aerial data available on MassGIS site [MassGIS Aerial Orthos](#). Coordinates are in Massachusetts State Plane Meters.

#### Examples: 1 band clipping

```
-- Clip the first band of an aerial tile by a 20 meter buffer.
SELECT ST_Clip(rast, 1,
 ST_Buffer(ST_Centroid(ST_Envelope(rast)),20)
) from aerials.boston
WHERE rid = 4;
```

```
-- Demonstrate effect of crop on final dimensions of raster
-- Note how final extent is clipped to that of the geometry
-- if crop = true
SELECT ST_XMax(ST_Envelope(ST_Clip(rast, 1, clipper, true))) As xmax_w_trim,
 ST_XMax(clipper) As xmax_clipper,
 ST_XMax(ST_Envelope(ST_Clip(rast, 1, clipper, false))) As xmax_wo_trim,
 ST_XMax(ST_Envelope(rast)) As xmax_rast_orig
FROM (SELECT rast, ST_Buffer(ST_Centroid(ST_Envelope(rast)),6) As clipper
FROM aerials.boston
WHERE rid = 6) As foo;
```

xmax_w_trim	xmax_clipper	xmax_wo_trim	xmax_rast_orig
230657.436173996	230657.436173996	230666.436173996	230666.436173996

*Full raster tile before clipping*

*After Clipping*

#### Examples: 1 band clipping with no crop and add back other bands unchanged

```
-- Same example as before, but we need to set crop to false to be able to use ST_AddBand
-- because ST_AddBand requires all bands be the same Width and height
SELECT ST_AddBand(ST_Clip(rast, 1,
 ST_Buffer(ST_Centroid(ST_Envelope(rast)),20),false
), ARRAY[ST_Band(rast,2),ST_Band(rast,3)]) from aerials.boston
WHERE rid = 6;
```

*Full raster tile before clipping*

*After Clipping - surreal*

#### Examples: Clip all bands

```
-- Clip all bands of an aerial tile by a 20 meter buffer.
-- Only difference is we don't specify a specific band to clip
-- so all bands are clipped
SELECT ST_Clip(rast,
 ST_Buffer(ST_Centroid(ST_Envelope(rast)), 20),
```

```

false
) from aerials.boston
WHERE rid = 4;

```

*Full raster tile before clipping*

*After Clipping*

#### 9.11.1.2 ST\_ColorMap

**ST\_ColorMap** — Creates a new raster of up to four 8BUI bands (grayscale, RGB, RGBA) from the source raster and a specified band. Band 1 is assumed if not specified.

### Synopsis

```
raster ST_ColorMap(raster rast, integer nband=1, text colormap=grayscale, text method=INTERPOLATE);
```

```
raster ST_ColorMap(raster rast, text colormap, text method=INTERPOLATE);
```

### Description

Apply a `colormap` to the band at `nband` of `rast` resulting a new raster comprised of up to four 8BUI bands. The number of 8BUI bands in the new raster is determined by the number of color components defined in `colormap`.

If `nband` is not specified, then band 1 is assumed.

`colormap` can be a keyword of a pre-defined colormap or a set of lines defining the value and the color components.

Valid pre-defined `colormap` keyword:

- `grayscale` or `greyscale` for a one 8BUI band raster of shades of gray.
- `pseudocolor` for a four 8BUI (RGBA) band raster with colors going from blue to green to red.
- `fire` for a four 8BUI (RGBA) band raster with colors going from black to red to pale yellow.

- `bluered` for a four 8BUI (RGBA) band raster with colors going from blue to pale white to red.

Users can pass a set of entries (one per line) to `colormap` to specify custom colormaps. Each entry generally consists of five values: the pixel value and corresponding Red, Green, Blue, Alpha components (color components between 0 and 255). Percent values can be used instead of pixel values where 0% and 100% are the minimum and maximum values found in the raster band. Values can be separated with commas (','), tabs, colons (':') and/or spaces. The pixel value can be set to `nv`, `null` or `nodata` for the NODATA value. An example is provided below.

```
5 0 0 0 255
4 100:50 55 255
1 150,100 150 255
0% 255 255 255 255
nv 0 0 0 0
```

The syntax of `colormap` is similar to that of the color-relief mode of GDAL `gdaldem`.

Valid keywords for `method`:

- `INTERPOLATE` to use linear interpolation to smoothly blend the colors between the given pixel values
- `EXACT` to strictly match only those pixels values found in the colormap. Pixels whose value does not match a colormap entry will be set to 0 0 0 0 (RGBA)
- `NEAREST` to use the colormap entry whose value is closest to the pixel value

#### Note

A great reference for colormaps is [ColorBrewer](#).

#### Warning

The resulting bands of new raster will have no NODATA value set. Use `ST_SetBandNoDataValue` to set a NODATA value if one is needed.

Availability: 2.1.0

## Examples

This is a junk table to play with

```
-- setup test raster table --
DROP TABLE IF EXISTS funky_shapes;
CREATE TABLE funky_shapes(rast raster);

INSERT INTO funky_shapes(rast)
WITH ref AS (
 SELECT ST_MakeEmptyRaster(200, 200, 0, 200, 1, -1, 0, 0) AS rast
)
SELECT
 ST_Union(rast)
FROM (
 SELECT
 ST_AsRaster(
 ST_Rotate(
 ST_Buffer(
 ST_GeomFromText('LINESTRING(0 2,50 50,150 150,125 50)'),
```

```

 i*2
),
 pi() * i * 0.125, ST_Point(50,50)
),
 ref.rast, '8BUI'::text, i * 5
) AS rast
FROM ref
CROSS JOIN generate_series(1, 10, 3) AS i
) AS shapes;

```

```

SELECT
 ST_NumBands(rast) As n_orig,

**9.11.1.3 ST\_Intersection**

`ST_Intersection` — Returns a raster or a set of geometry-pixelvalue pairs representing the shared portion of two rasters or the geometrical intersection of a vectorization of the raster and a geometry.

## Synopsis

```

setof geomval ST_Intersection(geometry geom, raster rast, integer band_num=1);
setof geomval ST_Intersection(raster rast, geometry geom);
setof geomval ST_Intersection(raster rast, integer band, geometry geom);
raster ST_Intersection(raster rast1, raster rast2, double precision[] nodataval);
raster ST_Intersection(raster rast1, raster rast2, text returnband, double precision[] nodataval);
raster ST_Intersection(raster rast1, integer band1, raster rast2, integer band2, double precision[] nodataval);
raster ST_Intersection(raster rast1, integer band1, raster rast2, integer band2, text returnband, double precision[] nodataval);

```

## Description

Returns a raster or a set of geometry-pixelvalue pairs representing the shared portion of two rasters or the geometrical intersection of a vectorization of the raster and a geometry.

The first three variants, returning a setof geomval, works in vector space. The raster is first vectorized (using `ST_DumpAsPolygon`) into a set of geomval rows and those rows are then intersected with the geometry using the `ST_Intersection(geometry, geometry)` PostGIS function. Geometries intersecting only with a nodata value area of a raster returns an empty geometry. They are normally excluded from the results by the proper usage of `ST_Intersect` in the `WHERE` clause.

You can access the geometry and the value parts of the resulting set of geomval by surrounding them with parenthesis and adding `'geom'` or `'val'` at the end of the expression. e.g. `(ST_Intersection(rast, geom)).geom`

The other variants, returning a raster, works in raster space. They are using the two rasters version of `ST_MapAlgebraExpr` to perform the intersection.

The extent of the resulting raster corresponds to the geometrical intersection of the two raster extents. The resulting raster includes `'BAND1'`, `'BAND2'` or `'BOTH'` bands, following what is passed as the `returnband` parameter. Nodata value areas present in any band results in nodata value areas in every bands of the result. In other words, any pixel intersecting with a nodata value pixel becomes a nodata value pixel in the result.

Rasters resulting from `ST_Intersection` must have a nodata value assigned for areas not intersecting. You can define or replace the nodata value for any resulting band by providing a `nodataval[]` array of one or two nodata values depending if you request `'BAND1'`, `'BAND2'` or `'BOTH'` bands. The first value in the array replace the nodata value in the first band and the second value replace the nodata value in the second band. If one input band do not have a nodata value defined and none are provided as an array, one is chosen using the `ST_MinPossibleValue` function. All variant accepting an array of nodata value can also accept a single value which will be assigned to each requested band.

In all variants, if no band number is specified band 1 is assumed. If you need an intersection between a raster and geometry that returns a raster, refer to [ST\\_Clip](#).

### Note

To get more control on the resulting extent or on what to return when encountering a nodata value, use the two rasters version of [ST\\_MapAlgebraExpr](#).

---

### Note

To compute the intersection of a raster band with a geometry in raster space, use [ST\\_Clip](#). `ST_Clip` works on multiple bands rasters and does not return a band corresponding to the rasterized geometry.

---

### Note

`ST_Intersection` should be used in conjunction with `ST_Intersects` and an index on the raster column and/or the geometry column.

---

Enhanced: 2.0.0 - Intersection in the raster space was introduced. In earlier pre-2.0.0 versions, only intersection performed in vector space were supported.

---

**Examples: Geometry, Raster -- resulting in geometry vals**

```

SELECT
 foo.rid,
 foo.gid,
 ST_AsText((foo.geomval).geom) As geomwkt,
 (foo.geomval).val
FROM (
 SELECT
 A.rid,
 g.gid,
 ST_Intersection(A.rast, g.geom) As geomval
 FROM dummy_rast AS A
 CROSS JOIN (
 VALUES
 (1, ST_Point(3427928, 5793243.85)),
 (2, ST_GeomFromText('LINESTRING(3427927.85 5793243.75,3427927.8 5793243.75,3427927.8 5793243.8)')),
 (3, ST_GeomFromText('LINESTRING(1 2, 3 4)'))
) As g(gid,geom)
 WHERE A.rid = 2
) As foo;

```

rid	gid	geomwkt	val
2	1	POINT(3427928 5793243.85)	249
2	1	POINT(3427928 5793243.85)	253
2	2	POINT(3427927.85 5793243.75)	254
2	2	POINT(3427927.8 5793243.8)	251
2	2	POINT(3427927.8 5793243.8)	253
2	2	LINESTRING(3427927.8 5793243.75,3427927.8 5793243.8)	252

**9.11.1.4 ST\_MapAlgebra**

**ST\_MapAlgebra** — Callback function version - Returns a one-band raster given one or more input rasters, band indexes and one user-specified callback function.

**Synopsis**

```

raster ST_MapAlgebra(rastbandarg[] rastbandargset, regprocedure callbackfunc, text pixeltype=NULL, text extenttype=INTERSECTION,
raster customextent=NULL, integer distancex=0, integer distancey=0, text[] VARIADIC userargs=NULL);
raster ST_MapAlgebra(raster rast, integer[] nband, regprocedure callbackfunc, text pixeltype=NULL, text extenttype=FIRST,
raster customextent=NULL, integer distancex=0, integer distancey=0, text[] VARIADIC userargs=NULL);
raster ST_MapAlgebra(raster rast, integer nband, regprocedure callbackfunc, text pixeltype=NULL, text extenttype=FIRST,
raster customextent=NULL, integer distancex=0, integer distancey=0, text[] VARIADIC userargs=NULL);
raster ST_MapAlgebra(raster rast1, integer nband1, raster rast2, integer nband2, regprocedure callbackfunc, text pixeltype=NULL,
text extenttype=INTERSECTION, raster customextent=NULL, integer distancex=0, integer distancey=0, text[] VARIADIC user-
args=NULL);
raster ST_MapAlgebra(nband integer, regprocedure callbackfunc, float8[] mask, boolean weighted, text pixeltype=NULL, text
extenttype=INTERSECTION, raster customextent=NULL, text[] VARIADIC userargs=NULL);

```

## Description

Returns a one-band raster given one or more input rasters, band indexes and one user-specified callback function.

**rast,rast1,rast2, rastbandargset** Rasters on which the map algebra process is evaluated.

`rastbandargset` allows the use of a map algebra operation on many rasters and/or many bands. See example Variant 1.

**nband, nband1, nband2** Band numbers of the raster to be evaluated. `nband` can be an integer or integer[] denoting the bands. `nband1` is band on `rast1` and `nband2` is band on `rast2` for hte 2 raster/2band case.

**callbackfunc** The `callbackfunc` parameter must be the name and signature of an SQL or PL/pgSQL function, cast to a regprocedure. An example PL/pgSQL function example is:

```
CREATE OR REPLACE FUNCTION sample_callbackfunc(value double precision[][][], position ←
integer[][], VARIADIC userargs text[])
RETURNS double precision
AS $$
BEGIN
RETURN 0;
END;
$$ LANGUAGE 'plpgsql' IMMUTABLE;
```

The `callbackfunc` must have three arguments: a 3-dimension double precision array, a 2-dimension integer array and a variadic 1-dimension text array. The first argument `value` is the set of values (as double precision) from all input rasters. The three dimensions (where indexes are 1-based) are: raster #, row y, column x. The second argument `position` is the set of pixel positions from the output raster and input rasters. The outer dimension (where indexes are 0-based) is the raster #. The position at outer dimension index 0 is the output raster's pixel position. For each outer dimension, there are two elements in the inner dimension for X and Y. The third argument `userargs` is for passing through any user-specified arguments.

Passing a regprocedure argument to a SQL function requires the full function signature to be passed, then cast to a regprocedure type. To pass the above example PL/pgSQL function as an argument, the SQL for the argument is:

```
'sample_callbackfunc(double precision[], integer[], text[])':regprocedure
```

Note that the argument contains the name of the function, the types of the function arguments, quotes around the name and argument types, and a cast to a regprocedure.

**mask** An n-dimensional array (matrix) of numbers used to filter what cells get passed to map algebra call-back function. 0 means a neighbor cell value should be treated as no-data and 1 means value should be treated as data. If `weight` is set to true, then the values, are used as multipliers to multiple the pixel value of that value in the neighborhood position.

**weighted** boolean (true/false) to denote if a mask value should be weighted (multiplied by original value) or not (only applies to proto that takes a mask).

**pixeltype** If `pixeltype` is passed in, the one band of the new raster will be of that pixeltype. If `pixeltype` is passed NULL or left out, the new raster band will have the same pixeltype as the specified band of the first raster (for extent types: INTERSECTION, UNION, FIRST, CUSTOM) or the specified band of the appropriate raster (for extent types: SECOND, LAST). If in doubt, always specify `pixeltype`.

The resulting pixel type of the output raster must be one listed in [ST\\_BandPixelType](#) or left out or set to NULL.

**extenttype** Possible values are INTERSECTION (default), UNION, FIRST (default for one raster variants), SECOND, LAST, CUSTOM.

**customextent** If `extenttype` is CUSTOM, a raster must be provided for `customextent`. See example 4 of Variant 1.

**distancex** The distance in pixels from the reference cell. So width of resulting matrix would be  $2*distancex + 1$ . If not specified only the reference cell is considered (neighborhood of 0).

**distancy** The distance in pixels from reference cell in y direction. Height of resulting matrix would be  $2*distancy + 1$ . If not specified only the reference cell is considered (neighborhood of 0).

**userargs** The third argument to the `callbackfunc` is a variadic text array. All trailing text arguments are passed through to the specified `callbackfunc`, and are contained in the `userargs` argument.

**Note**

For more information about the VARIADIC keyword, please refer to the PostgreSQL documentation and the "SQL Functions with Variable Numbers of Arguments" section of [Query Language \(SQL\) Functions](#).

**Note**

The `text[]` argument to the `callbackfunc` is required, regardless of whether you choose to pass any arguments to the callback function for processing or not.

Variant 1 accepts an array of `rastbandarg` allowing the use of a map algebra operation on many rasters and/or many bands. See example Variant 1.

Variants 2 and 3 operate upon one or more bands of one raster. See example Variant 2 and 3.

Variant 4 operate upon two rasters with one band per raster. See example Variant 4.

Availability: 2.2.0: Ability to add a mask

Availability: 2.1.0

**Examples: Variant 1****One raster, one band**

```
WITH foo AS (
 SELECT 1 AS rid, ST_AddBand(ST_MakeEmptyRaster(2, 2, 0, 0, 1, -1, 0, 0, 0), 1, '16BUI', 1, 0) AS rast
)
SELECT
 ST_MapAlgebra(
 ARRAY[ROW(rast, 1)]::rastbandarg[],
 'sample_callbackfunc(double precision[], int[], text[])'::regprocedure
) AS rast
FROM foo
```

**One raster, several bands**

```
WITH foo AS (
 SELECT 1 AS rid, ST_AddBand(ST_AddBand(ST_AddBand(ST_MakeEmptyRaster(2, 2, 0, 0, 1, -1, 0, 0, 0), 1, '16BUI', 1, 0), 2, '8BUI', 10, 0), 3, '32BUI', 100, 0) AS rast
)
SELECT
 ST_MapAlgebra(

#### 9.11.1.5 ST\_MapAlgebra

**ST\_MapAlgebra** — Expression version - Returns a one-band raster given one or two input rasters, band indexes and one or more user-specified SQL expressions.

## Synopsis

```
raster ST_MapAlgebra(raster rast, integer nband, text pixeltype, text expression, double precision nodataval=NULL);
raster ST_MapAlgebra(raster rast, text pixeltype, text expression, double precision nodataval=NULL);
raster ST_MapAlgebra(raster rast1, integer nband1, raster rast2, integer nband2, text expression, text pixeltype=NULL, text extenttype=INTERSECTION, text nodata1expr=NULL, text nodata2expr=NULL, double precision nodatanodataval=NULL);
raster ST_MapAlgebra(raster rast1, raster rast2, text expression, text pixeltype=NULL, text extenttype=INTERSECTION, text nodata1expr=NULL, text nodata2expr=NULL, double precision nodatanodataval=NULL);
```

## Description

Expression version - Returns a one-band raster given one or two input rasters, band indexes and one or more user-specified SQL expressions.

Availability: 2.1.0

### Description: Variants 1 and 2 (one raster)

Creates a new one band raster formed by applying a valid PostgreSQL algebraic operation defined by the `expression` on the input raster (`rast`). If `nband` is not provided, band 1 is assumed. The new raster will have the same georeference, width, and height as the original raster but will only have one band.

If `pixeltype` is passed in, then the new raster will have a band of that pixeltype. If `pixeltype` is passed NULL, then the new raster band will have the same pixeltype as the input `rast` band.

- Keywords permitted for `expression`
  1. `[rast]` - Pixel value of the pixel of interest
  2. `[rast.val]` - Pixel value of the pixel of interest
  3. `[rast.x]` - 1-based pixel column of the pixel of interest
  4. `[rast.y]` - 1-based pixel row of the pixel of interest

### Description: Variants 3 and 4 (two raster)

Creates a new one band raster formed by applying a valid PostgreSQL algebraic operation to the two bands defined by the `expression` on the two input raster bands `rast1`, (`rast2`). If no `band1`, `band2` is specified band 1 is assumed. The resulting raster will be aligned (scale, skew and pixel corners) on the grid defined by the first raster. The resulting raster will have the extent defined by the `extenttype` parameter.

**expression** A PostgreSQL algebraic expression involving the two rasters and PostgreSQL defined functions/operators that will define the pixel value when pixels intersect. e.g. `(([rast1] + [rast2])/2.0)::integer`

**pixeltype** The resulting pixel type of the output raster. Must be one listed in [ST\\_BandPixelType](#), left out or set to NULL. If not passed in or set to NULL, will default to the pixeltype of the first raster.

**extenttype** Controls the extent of resulting raster

1. `INTERSECTION` - The extent of the new raster is the intersection of the two rasters. This is the default.
2. `UNION` - The extent of the new raster is the union of the two rasters.
3. `FIRST` - The extent of the new raster is the same as the one of the first raster.
4. `SECOND` - The extent of the new raster is the same as the one of the second raster.

**nodata1expr** An algebraic expression involving only `rast2` or a constant that defines what to return when pixels of `rast1` are nodata values and spatially corresponding `rast2` pixels have values.

**nodata2expr** An algebraic expression involving only `rast1` or a constant that defines what to return when pixels of `rast2` are nodata values and spatially corresponding `rast1` pixels have values.

**nodatanodataval** A numeric constant to return when spatially corresponding rast1 and rast2 pixels are both nodata values.

• Keywords permitted in expression, nodataexpr and nodata2expr

1. [rast1] - Pixel value of the pixel of interest from rast1
2. [rast1.val] - Pixel value of the pixel of interest from rast1
3. [rast1.x] - 1-based pixel column of the pixel of interest from rast1
4. [rast1.y] - 1-based pixel row of the pixel of interest from rast1
5. [rast2] - Pixel value of the pixel of interest from rast2
6. [rast2.val] - Pixel value of the pixel of interest from rast2
7. [rast2.x] - 1-based pixel column of the pixel of interest from rast2
8. [rast2.y] - 1-based pixel row of the pixel of interest from rast2

### Examples: Variants 1 and 2

```
WITH foo AS (
 SELECT ST_AddBand(ST_MakeEmptyRaster(10, 10, 0, 0, 1, 1, 0, 0, 0), '32BF', 1, -1) AS rast
)
SELECT
 ST_MapAlgebra(rast, 1, NULL, 'ceil([rast]*[rast.x]/[rast.y]+[rast.val])')
FROM foo
```

### Examples: Variant 3 and 4

```
WITH foo AS (
 SELECT 1 AS rid, ST_AddBand(ST_AddBand(ST_AddBand(ST_MakeEmptyRaster(2, 2, 0, 0, 1, -1, ←
 0, 0, 0), 1, '16BUI', 1, 0), 2, '8BUI', 10, 0), 3, '32BUI', 100, 0) AS rast UNION ALL
 SELECT 2 AS rid, ST_AddBand(ST_AddBand(ST_AddBand(ST_MakeEmptyRaster(2, 2, 0, 1, 1, -1, ←
 0, 0, 0), 1, '16BUI', 2, 0), 2, '8BUI', 20, 0), 3, '32BUI', 300, 0) AS rast
)
SELECT
 ST_MapAlgebra(
 t1.rast, 2,
 t2.rast, 1,
 '([rast2] + [rast1.val]) / 2'
) AS rast
FROM foo t1
CROSS JOIN foo t2
WHERE t1.rid = 1
 AND t2.rid = 2
```

#### 9.11.1.6 ST\_MapAlgebraExpr

**ST\_MapAlgebraExpr** — 1 raster band version: Creates a new one band raster formed by applying a valid PostgreSQL algebraic operation on the input raster band and of pixeltype provided. Band 1 is assumed if no band is specified.

### Synopsis

```
raster ST_MapAlgebraExpr(raster rast, integer band, text pixeltype, text expression, double precision nodataval=NULL);
raster ST_MapAlgebraExpr(raster rast, text pixeltype, text expression, double precision nodataval=NULL);
```

## Description

### Warning

`ST_MapAlgebraExpr` is deprecated as of 2.1.0. Use `ST_MapAlgebra` instead.

Creates a new one band raster formed by applying a valid PostgreSQL algebraic operation defined by the `expression` on the input raster (`rast`). If no band is specified band 1 is assumed. The new raster will have the same georeference, width, and height as the original raster but will only have one band.

If `pixeltype` is passed in, then the new raster will have a band of that pixeltype. If `pixeltype` is passed NULL, then the new raster band will have the same pixeltype as the input `rast` band.

In the expression you can use the term `[rast]` to refer to the pixel value of the original band, `[rast.x]` to refer to the 1-based pixel column index, `[rast.y]` to refer to the 1-based pixel row index.

Availability: 2.0.0

## Examples

Create a new 1 band raster from our original that is a function of modulo 2 of the original raster band.

```
ALTER TABLE dummy_rast ADD COLUMN map_rast raster;
UPDATE dummy_rast SET map_rast = ST_MapAlgebraExpr(rast,NULL,'mod([rast],2)') WHERE rid = 2;
```

```
SELECT
 ST_Value(rast,1,i,j) As origval,
 ST_Value(map_rast, 1, i, j) As mapval
FROM dummy_rast
CROSS JOIN generate_series(1, 3) AS i
CROSS JOIN generate_series(1,3) AS j
WHERE rid = 2;
```

origval	mapval
253	1
254	0
253	1
253	1
254	0
254	0
250	0
254	0
254	0

Create a new 1 band raster of pixel-type 2BUI from our original that is reclassified and set the nodata value to be 0.

```
ALTER TABLE dummy_rast ADD COLUMN map_rast2 raster;
UPDATE dummy_rast SET
 map_rast2 = ST_MapAlgebraExpr(rast,'2BUI','CASE WHEN [rast] BETWEEN 100 and 250 THEN 1
 WHEN [rast] = 252 THEN 2 WHEN [rast] BETWEEN 253 and 254 THEN 3 ELSE 0 END', '0')
WHERE rid = 2;
```

```
SELECT DISTINCT
 ST_Value(rast,1,i,j) As origval,
 ST_Value(map_rast2, 1, i, j) As mapval
FROM dummy_rast
CROSS JOIN generate_series(1, 5) AS i
```

```
CROSS JOIN generate_series(1,5) AS j
WHERE rid = 2;
```

original	mapval
249	1
250	1
251	1
252	2
253	3
254	3

```
SELECT
 ST_BandPixelType(map_rast2) As b1pixtyp
FROM dummy_rast
WHERE rid = 2;
```

b1pixtyp
2BUI

*original (column rast-view)*

*rast\_view\_ma*

Create a new 3 band raster same pixel type from our original 3 band raster with first band altered by map algebra and remaining 2 bands unaltered.

```
SELECT
 ST_AddBand(
 ST_AddBand(
 ST_AddBand(
 ST_MakeEmptyRaster(rast_view),
 ST_MapAlgebraExpr(rast_view,1,NULL,'tan([rast])*[rast]')
),
 ST_Band(rast_view,2)
),

**9.11.1.7 ST\_MapAlgebraExpr**

**ST\_MapAlgebraExpr** — 2 raster band version: Creates a new one band raster formed by applying a valid PostgreSQL algebraic operation on the two input raster bands and of pixeltype provided. band 1 of each raster is assumed if no band numbers are specified. The resulting raster will be aligned (scale, skew and pixel corners) on the grid defined by the first raster and have its extent defined by the "extenttype" parameter. Values for "extenttype" can be: INTERSECTION, UNION, FIRST, SECOND.

**Synopsis**

raster **ST\_MapAlgebraExpr**(raster rast1, raster rast2, text expression, text pixeltype=same\_as\_rast1\_band, text extenttype=INTERSECTION, text nodata1expr=NULL, text nodata2expr=NULL, double precision nodatanodataval=NULL);  
 raster **ST\_MapAlgebraExpr**(raster rast1, integer band1, raster rast2, integer band2, text expression, text pixeltype=same\_as\_rast1\_band, text extenttype=INTERSECTION, text nodata1expr=NULL, text nodata2expr=NULL, double precision nodatanodataval=NULL);

**Description****Warning**

**ST\_MapAlgebraExpr** is deprecated as of 2.1.0. Use [ST\\_MapAlgebra](#) instead.

Creates a new one band raster formed by applying a valid PostgreSQL algebraic operation to the two bands defined by the `expression` on the two input raster bands `rast1`, (`rast2`). If no `band1`, `band2` is specified band 1 is assumed. The resulting raster will be aligned (scale, skew and pixel corners) on the grid defined by the first raster. The resulting raster will have the extent defined by the `extenttype` parameter.

**expression** A PostgreSQL algebraic expression involving the two rasters and PostgreSQL defined functions/operators that will define the pixel value when pixels intersect. e.g. `(([rast1] + [rast2])/2.0)::integer`

**pixeltype** The resulting pixel type of the output raster. Must be one listed in [ST\\_BandPixelType](#), left out or set to NULL. If not passed in or set to NULL, will default to the pixeltype of the first raster.

**extenttype** Controls the extent of resulting raster

1. INTERSECTION - The extent of the new raster is the intersection of the two rasters. This is the default.
2. UNION - The extent of the new raster is the union of the two rasters.
3. FIRST - The extent of the new raster is the same as the one of the first raster.
4. SECOND - The extent of the new raster is the same as the one of the second raster.

**nodata1expr** An algebraic expression involving only `rast2` or a constant that defines what to return when pixels of `rast1` are nodata values and spatially corresponding `rast2` pixels have values.

**nodata2expr** An algebraic expression involving only `rast1` or a constant that defines what to return when pixels of `rast2` are nodata values and spatially corresponding `rast1` pixels have values.

**nodatanodataval** A numeric constant to return when spatially corresponding `rast1` and `rast2` pixels are both nodata values.

If `pixeltype` is passed in, then the new raster will have a band of that pixeltype. If `pixeltype` is passed NULL or no pixel type specified, then the new raster band will have the same pixeltype as the input `rast1` band.

Use the term `[rast1.val]` `[rast2.val]` to refer to the pixel value of the original raster bands and `[rast1.x]`, `[rast1.y]` etc. to refer to the column / row positions of the pixels.

Availability: 2.0.0

**Example: 2 Band Intersection and Union**

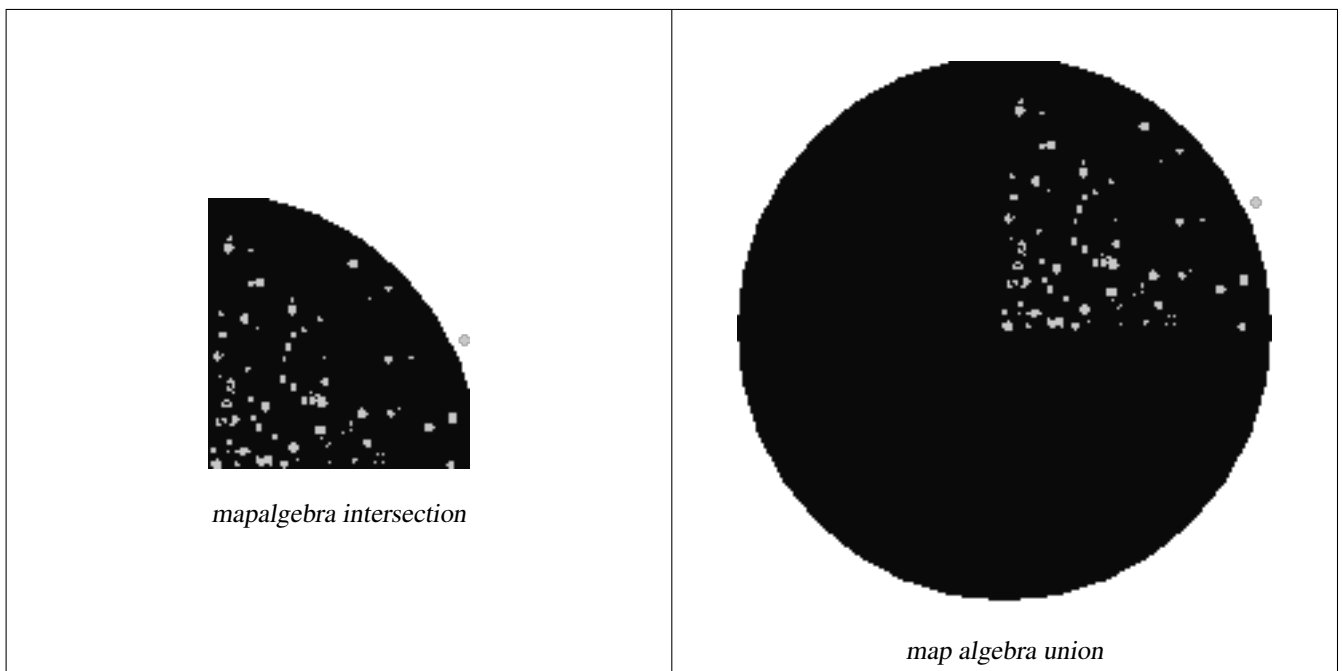

Create a new 1 band raster from our original that is a function of modulo 2 of the original raster band.

```
--Create a cool set of rasters --
DROP TABLE IF EXISTS fun_shapes;
CREATE TABLE fun_shapes(rid serial PRIMARY KEY, fun_name text, rast raster);

-- Insert some cool shapes around Boston in Massachusetts state plane meters --
INSERT INTO fun_shapes(fun_name, rast)
VALUES ('ref', ST_AsRaster(ST_MakeEnvelope(235229, 899970, 237229, 901930,26986),200,200,'8BUI',0,0));

INSERT INTO fun_shapes(fun_name,rast)
WITH ref(rast) AS (SELECT rast FROM fun_shapes WHERE fun_name = 'ref')
SELECT 'area' AS fun_name, ST_AsRaster(ST_Buffer(ST_SetSRID(ST_Point(236229, 900930),26986)
, 1000),
ref.rast,'8BUI', 10, 0) As rast
FROM ref
UNION ALL
SELECT 'rand bubbles',

area.rast, bub.rast, '[rast2.val]', '8BUI', 'UNION', '[rast2.val]', '[rast1.val]') As unionrast
FROM
(SELECT rast FROM fun_shapes WHERE
fun_name = 'area') As area
CROSS JOIN (SELECT rast
FROM fun_shapes WHERE
fun_name = 'rand bubbles') As bub
```

*mapalgebra intersection**map algebra union***Example: Overlaying rasters on a canvas as separate bands**

```
-- we use ST_AsPNG to render the image so all single band ones look grey --
WITH mygeoms
 AS (SELECT 2 As bnum, ST_Buffer(ST_Point(1,5),10) As geom
 UNION ALL
 SELECT 3 AS bnum,
 ST_Buffer(ST_GeomFromText('LINESTRING(50 50,150 150,150 50)'), 10,'join=↔
 bevel') As geom
 UNION ALL
 SELECT 1 As bnum,
 ST_Buffer(ST_GeomFromText('LINESTRING(60 50,150 150,150 50)'), 5,'join=↔
 bevel') As geom
),
-- define our canvas to be 1 to 1 pixel to geometry
canvas
 AS (SELECT ST_AddBand(ST_MakeEmptyRaster(200,
 200,
 ST_XMin(e)::integer, ST_YMax(e)::integer, 1, -1, 0, 0) , '8BUI'::text,0) As rast
 FROM (SELECT ST_Extent(geom) As e,
 Max(ST_SRID(geom)) As srid
 from mygeoms
) As foo
),
rbands AS (SELECT ARRAY(SELECT ST_MapAlgebraExpr(canvas.rast, ST_AsRaster(m.geom, canvas ←
.rast, '8BUI', 100),
 '[rast2.val]', '8BUI', 'FIRST', '[rast2.val]', '[rast1.val]') As rast
 FROM mygeoms AS m CROSS JOIN canvas
 ORDER BY m.bnum) As rasts
)
 SELECT rasts[1] As rast1 , rasts[2] As rast2, rasts[3] As rast3, ST_AddBand(
 ST_AddBand(rasts[1],rasts[2]), rasts[3]) As final_rast
 FROM rbands;
```

### Example: Overlay 2 meter boundary of select parcels over an aerial imagery

```
-- Create new 3 band raster composed of first 2 clipped bands, and overlay of 3rd band with ←
 our geometry
-- This query took 3.6 seconds on PostGIS windows 64-bit install
WITH pr AS
-- Note the order of operation: we clip all the rasters to dimensions of our region
(SELECT ST_Clip(rast,ST_Expand(geom,50)) As rast, g.geom
 FROM aerials.o_2_boston AS r INNER JOIN
-- union our parcels of interest so they form a single geometry we can later intersect with
 (SELECT ST_Union(ST_Transform(the_geom,26986)) AS geom
 FROM landparcels WHERE pid IN('0303890000', '0303900000')) As g
 ON ST_Intersects(rast::geometry, ST_Expand(g.geom,50))
),
-- we then union the raster shards together
```

```

-- ST_Union on raster is kinda of slow but much faster the smaller you can get the rasters
-- therefore we want to clip first and then union
prunion AS
(SELECT ST_AddBand(NULL, ARRAY[ST_Union(rast,1),ST_Union(rast,2),ST_Union(rast,3)]) As ←
 clipped,geom
FROM pr
GROUP BY geom)
-- return our final raster which is the unioned shard with
-- with the overlay of our parcel boundaries
-- add first 2 bands, then mapalgebra of 3rd band + geometry
SELECT ST_AddBand(ST_Band(clipped,ARRAY[1,2])
 , ST_MapAlgebraExpr(ST_Band(clipped,3), ST_AsRaster(ST_Buffer(ST_Boundary(geom),2), ←
 clipped, '8BUI',250),
 '[rast2.val]', '8BUI', 'FIRST', '[rast2.val]', '[rast1.val]')) As rast
FROM prunion;

```

*The blue lines are the boundaries of select parcels*

raster ST_MapAlgebraFct(raster rast, integer band, text pixeltype, regprocedure onerasteruserfunc);
raster ST_MapAlgebraFct(raster rast, integer band, text pixeltype, regprocedure onerasteruserfunc, text[] VARIADIC args);
```

## Description

### Warning

`ST_MapAlgebraFct` is deprecated as of 2.1.0. Use `ST_MapAlgebra` instead.

Creates a new one band raster formed by applying a valid PostgreSQL function specified by the `onerasteruserfunc` on the input raster (`rast`). If no band is specified, band 1 is assumed. The new raster will have the same georeference, width, and height as the original raster but will only have one band.

If `pixeltype` is passed in, then the new raster will have a band of that pixeltype. If `pixeltype` is passed NULL, then the new raster band will have the same pixeltype as the input `rast` band.

The `onerasteruserfunc` parameter must be the name and signature of a SQL or PL/pgSQL function, cast to a regprocedure. A very simple and quite useless PL/pgSQL function example is:

```
CREATE OR REPLACE FUNCTION simple_function(pixel FLOAT, pos INTEGER[], VARIADIC args TEXT ←
[])
RETURNS FLOAT
AS $$ BEGIN
 RETURN 0.0;
END; $$
LANGUAGE 'plpgsql' IMMUTABLE;
```

The `userfunction` may accept two or three arguments: a float value, an optional integer array, and a variadic text array. The first argument is the value of an individual raster cell (regardless of the raster datatype). The second argument is the position of the current processing cell in the form '`{x,y}`'. The third argument indicates that all remaining parameters to `ST_MapAlgebraFct` shall be passed through to the `userfunction`.

Passing a regprocedure argument to a SQL function requires the full function signature to be passed, then cast to a regprocedure type. To pass the above example PL/pgSQL function as an argument, the SQL for the argument is:

```
'simple_function(float,integer[],text[])':regprocedure
```

Note that the argument contains the name of the function, the types of the function arguments, quotes around the name and argument types, and a cast to a regprocedure.

The third argument to the `userfunction` is a variadic text array. All trailing text arguments to any `ST_MapAlgebraFct` call are passed through to the specified `userfunction`, and are contained in the `args` argument.

### Note

For more information about the VARIADIC keyword, please refer to the PostgreSQL documentation and the "SQL Functions with Variable Numbers of Arguments" section of [Query Language \(SQL\) Functions](#).

### Note

The `text[]` argument to the `userfunction` is required, regardless of whether you choose to pass any arguments to your user function for processing or not.

Availability: 2.0.0

## Examples

Create a new 1 band raster from our original that is a function of modulo 2 of the original raster band.

```
ALTER TABLE dummy_rast ADD COLUMN map_rast raster;

#### 9.11.1.9 ST\_MapAlgebraFct

**ST\_MapAlgebraFct** — 2 band version - Creates a new one band raster formed by applying a valid PostgreSQL function on the 2 input raster bands and of pixeltype provided. Band 1 is assumed if no band is specified. Extent type defaults to INTERSECTION if not specified.

### Synopsis

raster **ST\_MapAlgebraFct**(raster rast1, raster rast2, regprocedure tworastuserfunc, text pixeltype=same\_as\_rast1, text extenttype=INTERSECTION, text[] VARIADIC userargs);

raster **ST\_MapAlgebraFct**(raster rast1, integer band1, raster rast2, integer band2, regprocedure tworastuserfunc, text pixeltype=same\_as\_rast1, text extenttype=INTERSECTION, text[] VARIADIC userargs);

### Description

#### Warning

**ST\_MapAlgebraFct** is deprecated as of 2.1.0. Use [ST\\_MapAlgebra](#) instead.

Creates a new one band raster formed by applying a valid PostgreSQL function specified by the `tworastuserfunc` on the input raster `rast1`, `rast2`. If no `band1` or `band2` is specified, band 1 is assumed. The new raster will have the same georeference, width, and height as the original rasters but will only have one band.

If `pixeltype` is passed in, then the new raster will have a band of that pixeltype. If `pixeltype` is passed NULL or left out, then the new raster band will have the same pixeltype as the input `rast1` band.

The `tworastuserfunc` parameter must be the name and signature of an SQL or PL/pgSQL function, cast to a regprocedure. An example PL/pgSQL function example is:

```

CREATE OR REPLACE FUNCTION simple_function_for_two_rasters(pixel1 FLOAT, pixel2 FLOAT, pos ←
 INTEGER[], VARIADIC args TEXT[])
 RETURNS FLOAT
 AS $$ BEGIN
 RETURN 0.0;
 END; $$
LANGUAGE 'plpgsql' IMMUTABLE;

```

The `tworastuserfunc` may accept three or four arguments: a double precision value, a double precision value, an optional integer array, and a variadic text array. The first argument is the value of an individual raster cell in `rast1` (regardless of the raster datatype). The second argument is an individual raster cell value in `rast2`. The third argument is the position of the

current processing cell in the form '{x,y}'. The fourth argument indicates that all remaining parameters to `ST_MapAlgebraFct` shall be passed through to the `tworastuserfunc`.

Passing a regprocedure argument to a SQL function requires the full function signature to be passed, then cast to a regprocedure type. To pass the above example PL/pgSQL function as an argument, the SQL for the argument is:

```
'simple_function(double precision, double precision, integer[], text[])::regprocedure
```

Note that the argument contains the name of the function, the types of the function arguments, quotes around the name and argument types, and a cast to a regprocedure.

The fourth argument to the `tworastuserfunc` is a variadic text array. All trailing text arguments to any `ST_MapAlgebraFct` call are passed through to the specified `tworastuserfunc`, and are contained in the `userargs` argument.

#### Note

For more information about the VARIADIC keyword, please refer to the PostgreSQL documentation and the "SQL Functions with Variable Numbers of Arguments" section of [Query Language \(SQL\) Functions](#).

#### Note

The `text[]` argument to the `tworastuserfunc` is required, regardless of whether you choose to pass any arguments to your user function for processing or not.

#### 9.11.1.10 ST\_MapAlgebraFctNgb

**ST\_MapAlgebraFctNgb** — 1-band version: Map Algebra Nearest Neighbor using user-defined PostgreSQL function. Return a raster which values are the result of a PLPGSQL user function involving a neighborhood of values from the input raster band.

### Synopsis

raster **ST\_MapAlgebraFctNgb**(raster rast, integer band, text pixeltype, integer ngbwidth, integer ngbheight, regprocedure on-erastngbuserfunc, text nodatamode, text[] VARIADIC args);

### Description

#### Warning

**ST\_MapAlgebraFctNgb** is deprecated as of 2.1.0. Use [ST\\_MapAlgebra](#) instead.

(one raster version) Return a raster which values are the result of a PLPGSQL user function involving a neighborhood of values from the input raster band. The user function takes the neighborhood of pixel values as an array of numbers, for each pixel, returns the result from the user function, replacing pixel value of currently inspected pixel with the function result.

**rast** Raster on which the user function is evaluated.

**band** Band number of the raster to be evaluated. Default to 1.

**pixeltype** The resulting pixel type of the output raster. Must be one listed in [ST\\_BandPixelType](#) or left out or set to NULL. If not passed in or set to NULL, will default to the pixeltype of the `rast`. Results are truncated if they are larger than what is allowed for the pixeltype.

**ngbwidth** The width of the neighborhood, in cells.

**ngbheight** The height of the neighborhood, in cells.

**onerastngbuserfunc** PLPGSQL/psql user function to apply to neighborhood pixels of a single band of a raster. The first element is a 2-dimensional array of numbers representing the rectangular pixel neighborhood

**nodatamode** Defines what value to pass to the function for a neighborhood pixel that is nodata or NULL

'ignore': any NODATA values encountered in the neighborhood are ignored by the computation -- this flag must be sent to the user callback function, and the user function decides how to ignore it.

'NULL': any NODATA values encountered in the neighborhood will cause the resulting pixel to be NULL -- the user callback function is skipped in this case.

'value': any NODATA values encountered in the neighborhood are replaced by the reference pixel (the one in the center of the neighborhood). Note that if this value is NODATA, the behavior is the same as 'NULL' (for the affected neighborhood)

**args** Arguments to pass into the user function.

Availability: 2.0.0

## Examples

Examples utilize the `katrina` raster loaded as a single tile described in [http://trac.osgeo.org/gdal/wiki/frmts\\_wtkraster.html](http://trac.osgeo.org/gdal/wiki/frmts_wtkraster.html) and then prepared in the [ST\\_Rescale](#) examples

```
--
-- A simple 'callback' user function that averages up all the values in a neighborhood.
--
CREATE OR REPLACE FUNCTION rast_avg(matrix float[][], nodatamode text, variadic args text ←
[])
RETURNS float AS
$$
DECLARE
_matrix float[][];
 x1 integer;
 x2 integer;
 y1 integer;
 y2 integer;
 sum float;
BEGIN
_matrix := matrix;
 sum := 0;
 FOR x in array_lower(matrix, 1)..array_upper(matrix, 1) LOOP
 FOR y in array_lower(matrix, 2)..array_upper(matrix, 2) LOOP
 sum := sum + _matrix[x][y];
 END LOOP;
 END LOOP;
 RETURN (sum*1.0/(array_upper(matrix,1)*array_upper(matrix,2)))::integer ;
END;
$$
LANGUAGE 'plpgsql' IMMUTABLE COST 1000;

-- now we apply to our raster averaging pixels within 2 pixels of each other in X and Y ←
direction --
SELECT ST_MapAlgebraFctNgb(rast, 1, '8BUI', 4,4,
```

```
'rast_avg(float[][], text, text[])'::regprocedure, 'NULL', NULL) As nn_with_border
FROM katrinas_rescaled
limit 1;
```

*First band of our raster*

*new raster after averaging pixels withing 4x4 pixels of each other*

#### 9.11.1.11 ST\_Reclass

**ST\_Reclass** — Creates a new raster composed of band types reclassified from original. The `nband` is the band to be changed. If `nband` is not specified assumed to be 1. All other bands are returned unchanged. Use case: convert a 16BUI band to a 8BUI and so forth for simpler rendering as viewable formats.

#### Synopsis

```
raster ST_Reclass(raster rast, integer nband, text reclassexpr, text pixeltype, double precision nodataval=NULL);
raster ST_Reclass(raster rast, reclassarg[] VARIADIC reclassargset);
raster ST_Reclass(raster rast, text reclassexpr, text pixeltype);
```

#### Description

Creates a new raster formed by applying a valid PostgreSQL algebraic operation defined by the `reclassexpr` on the input raster (`rast`). If no `band` is specified band 1 is assumed. The new raster will have the same georeference, width, and height as the original raster. Bands not designated will come back unchanged. Refer to [reclassarg](#) for description of valid reclassification expressions.

The bands of the new raster will have pixel type of `pixeltype`. If `reclassargset` is passed in then each `reclassarg` defines behavior of each band generated.

Availability: 2.0.0

**Examples Basic**

Create a new raster from the original where band 2 is converted from 8BUI to 4BUI and all values from 101-254 are set to nodata value.

```
ALTER TABLE dummy_rast ADD COLUMN reclass_rast raster;
UPDATE dummy_rast SET reclass_rast = ST_Reclass(rast,2,'0-87:1-10, 88-100:11-15, ←
 101-254:0-0', '4BUI',0) WHERE rid = 2;

SELECT i as col, j as row, ST_Value(rast,2,i,j) As origval,
 ST_Value(reclass_rast, 2, i, j) As reclassval,
 ST_Value(reclass_rast, 2, i, j, false) As reclassval_include_nodata
FROM dummy_rast CROSS JOIN generate_series(1, 3) AS i CROSS JOIN generate_series(1,3) AS j
WHERE rid = 2;
```

col	row	origval	reclassval	reclassval_include_nodata
1	1	78	9	9
2	1	98	14	14
3	1	122		0
1	2	96	14	14
2	2	118		0
3	2	180		0
1	3	99	15	15
2	3	112		0
3	3	169		0

**Example: Advanced using multiple reclassargs**

Create a new raster from the original where band 1,2,3 is converted to 1BB,4BUI, 4BUI respectively and reclassified. Note this uses the variadic reclassarg argument which can take as input an indefinite number of reclassargs (theoretically as many bands as you have)

```
UPDATE dummy_rast SET reclass_rast =
 ST_Reclass(rast,
 ROW(2,'0-87]:1-10, (87-100]:11-15, (101-254]:0-0', '4BUI',NULL)::reclassarg,
 ROW(1,'0-253]:1, 254:0', '1BB', NULL)::reclassarg,
 ROW(3,'0-70]:1, (70-86:2, [86-150]:3, [150-255:4', '4BUI', NULL)::reclassarg
) WHERE rid = 2;

SELECT i as col, j as row,ST_Value(rast,1,i,j) As ov1, ST_Value(reclass_rast, 1, i, j) As ←
 rv1,
 ST_Value(rast,2,i,j) As ov2, ST_Value(reclass_rast, 2, i, j) As rv2,
 ST_Value(rast,3,i,j) As ov3, ST_Value(reclass_rast, 3, i, j) As rv3
FROM dummy_rast CROSS JOIN generate_series(1, 3) AS i CROSS JOIN generate_series(1,3) AS j
WHERE rid = 2;
```

col	row	ov1	rv1	ov2	rv2	ov3	rv3
1	1	253	1	78	9	70	1
2	1	254	0	98	14	86	3
3	1	253	1	122	0	100	3
1	2	253	1	96	14	80	2
2	2	254	0	118	0	108	3
3	2	254	0	180	0	162	4
1	3	250	1	99	15	90	3
2	3	254	0	112	0	108	3
3	3	254	0	169	0	175	4

**Example: Advanced Map a single band 32BF raster to multiple viewable bands**

Create a new 3 band (8BUI,8BUI,8BUI viewable raster) from a raster that has only one 32bf band

```
ALTER TABLE wind ADD COLUMN rast_view raster;
UPDATE wind
 set rast_view = ST_AddBand(NULL,
 ARRAY[
 ST_Reclass(rast, 1, '0.1-10]:1-10,9-10]:11, (11-33:0'::text, '8BUI'::text,0),
 ST_Reclass(rast,1, '11-33):0-255, [0-32:0, (34-1000:0'::text, '8BUI'::text,0),
 ST_Reclass(rast,1, '0-32]:0, (32-100:100-255'::text, '8BUI'::text,0)
]
);
```

**See Also**

[ST\\_AddBand](#), [ST\\_Band](#), [ST\\_BandPixelType](#), [ST\\_MakeEmptyRaster](#), [reclassarg](#), [ST\\_Value](#)

**9.11.1.12 ST\_Union**

**ST\_Union** — Returns the union of a set of raster tiles into a single raster composed of 1 or more bands.

**Synopsis**

```
raster ST_Union(setof raster rast);
raster ST_Union(setof raster rast, unionarg[] unionargset);
raster ST_Union(setof raster rast, integer nband);
raster ST_Union(setof raster rast, text uniontype);
raster ST_Union(setof raster rast, integer nband, text uniontype);
```

**Description**

Returns the union of a set of raster tiles into a single raster composed of at least one band. The resulting raster's extent is the extent of the whole set. In the case of intersection, the resulting value is defined by `uniontype` which is one of the following: LAST (default), FIRST, MIN, MAX, COUNT, SUM, MEAN, RANGE.

**Note**

In order for rasters to be unioned, they must all have the same alignment. Use [ST\\_SameAlignment](#) and [ST\\_NotSameAlignmentReason](#) for more details and help. One way to fix alignment issues is to use [ST\\_Resample](#) and use the same reference raster for alignment.

Availability: 2.0.0

Enhanced: 2.1.0 Improved Speed (fully C-Based).

Availability: 2.1.0 `ST_Union(rast, unionarg)` variant was introduced.

Enhanced: 2.1.0 `ST_Union(rast)` (variant 1) unions all bands of all input rasters. Prior versions of PostGIS assumed the first band.

Enhanced: 2.1.0 `ST_Union(rast, uniontype)` (variant 4) unions all bands of all input rasters.

**Examples: Reconstitute a single band chunked raster tile**

```
-- this creates a single band from first band of raster tiles
-- that form the original file system tile
SELECT filename, ST_Union(rast,1) As file_rast
FROM sometable WHERE filename IN('dem01', 'dem02') GROUP BY filename;
```

**Examples: Return a multi-band raster that is the union of tiles intersecting geometry**

```
-- this creates a multi band raster collecting all the tiles that intersect a line
-- Note: In 2.0, this would have just returned a single band raster
-- , new union works on all bands by default
-- this is equivalent to unionarg: ARRAY[ROW(1, 'LAST'), ROW(2, 'LAST'), ROW(3, 'LAST')]:: ←
 unionarg[]
SELECT ST_Union(rast)
FROM aerials.boston
WHERE ST_Intersects(rast, ST_GeomFromText('LINESTRING(230486 887771, 230500 88772)',26986) ←
);
```

**Examples: Return a multi-band raster that is the union of tiles intersecting geometry**

Here we use the longer syntax if we only wanted a subset of bands or we want to change order of bands

```
-- this creates a multi band raster collecting all the tiles that intersect a line
SELECT ST_Union(rast,ARRAY[ROW(2, 'LAST'), ROW(1, 'LAST'), ROW(3, 'LAST')]::unionarg[])
FROM aerials.boston
WHERE ST_Intersects(rast, ST_GeomFromText('LINESTRING(230486 887771, 230500 88772)',26986) ←
);
```

**9.11.2 Built-in Map Algebra Callback Functions****9.11.2.1 ST\_Distinct4ma**

`ST_Distinct4ma` — Raster processing function that calculates the number of unique pixel values in a neighborhood.

**Synopsis**

```
float8 ST_Distinct4ma(float8[][] matrix, text nodatamode, text[] VARIADIC args);
double precision ST_Distinct4ma(double precision[][][] value, integer[][] pos, text[] VARIADIC userargs);
```

**Description**

Calculate the number of unique pixel values in a neighborhood of pixels.

**Note**

Variant 1 is a specialized callback function for use as a callback parameter to [ST\\_MapAlgebraFctNgb](#).

**Note**

Variant 2 is a specialized callback function for use as a callback parameter to [ST\\_MapAlgebra](#).

**Warning**

Use of Variant 1 is discouraged since [ST\\_MapAlgebraFctNgb](#) has been deprecated as of 2.1.0.

Availability: 2.0.0

Enhanced: 2.1.0 Addition of Variant 2

**Examples**

```
SELECT
 rid,
 st_value(
 st_mapalgebrafctngb(rast, 1, NULL, 1, 1, 'st_distinct4ma(float[][],text,text[])':: ↵
 regprocedure, 'ignore', NULL), 2, 2
)
FROM dummy_rast
WHERE rid = 2;
 rid | st_value
-----+-----
 2 | 3
(1 row)
```

**See Also**

**9.11.2.2 ST\_InvDistWeight4ma**

**ST\_InvDistWeight4ma** — Raster processing function that interpolates a pixel's value from the pixel's neighborhood.

**Synopsis**

double precision **ST\_InvDistWeight4ma**(double precision[][][] value, integer[][] pos, text[] VARIADIC userargs);

**Description**

Calculate an interpolated value for a pixel using the Inverse Distance Weighted method.

There are two optional parameters that can be passed through `userargs`. The first parameter is the power factor (variable `k` in the equation below) between 0 and 1 used in the Inverse Distance Weighted equation. If not specified, default value is 1. The second parameter is the weight percentage applied only when the value of the pixel of interest is included with the interpolated value from the neighborhood. If not specified and the pixel of interest has a value, that value is returned.

The basic inverse distance weight equation is:

$$\hat{z}(x_o) = \frac{\sum_{j=1}^m z(x_j) d_{ij}^{-k}}{\sum_{j=1}^m d_{ij}^{-k}}$$

$k$  = power factor, a real number between 0 and 1

#### Note

This function is a specialized callback function for use as a callback parameter to [ST\\_MapAlgebra](#).

Availability: 2.1.0

#### Examples

```
-- NEEDS EXAMPLE
```

#### See Also

#### 9.11.2.3 ST\_Max4ma

`ST_Max4ma` — Raster processing function that calculates the maximum pixel value in a neighborhood.

#### Synopsis

float8 `ST_Max4ma`(float8[][] matrix, text nodatamode, text[] VARIADIC args);  
double precision `ST_Max4ma`(double precision[][][] value, integer[][] pos, text[] VARIADIC userargs);

#### Description

Calculate the maximum pixel value in a neighborhood of pixels.

For Variant 2, a substitution value for NODATA pixels can be specified by passing that value to userargs.

#### Note

Variant 1 is a specialized callback function for use as a callback parameter to [ST\\_MapAlgebraFctNgb](#).

#### Note

Variant 2 is a specialized callback function for use as a callback parameter to [ST\\_MapAlgebra](#).

#### Warning

Use of Variant 1 is discouraged since [ST\\_MapAlgebraFctNgb](#) has been deprecated as of 2.1.0.

Availability: 2.0.0

Enhanced: 2.1.0 Addition of Variant 2

## Examples

```
SELECT
 rid,
 st_value(
 st_mapalgebrafctngb(rast, 1, NULL, 1, 1, 'st_max4ma(float[][],text,text[])':: ↵
 regprocedure, 'ignore', NULL), 2, 2
)
FROM dummy_rast
WHERE rid = 2;

### 9.11.2.4 ST\_Mean4ma

**ST\_Mean4ma** — Raster processing function that calculates the mean pixel value in a neighborhood.

## Synopsis

float8 **ST\_Mean4ma**(float8[][] matrix, text nodatamode, text[] VARIADIC args);

double precision **ST\_Mean4ma**(double precision[][][] value, integer[][] pos, text[] VARIADIC userargs);

## Description

Calculate the mean pixel value in a neighborhood of pixels.

For Variant 2, a substitution value for NODATA pixels can be specified by passing that value to userargs.

### Note

Variant 1 is a specialized callback function for use as a callback parameter to [ST\\_MapAlgebraFctNgb](#).

### Note

Variant 2 is a specialized callback function for use as a callback parameter to [ST\\_MapAlgebra](#).

### Warning

Use of Variant 1 is discouraged since [ST\\_MapAlgebraFctNgb](#) has been deprecated as of 2.1.0.

Availability: 2.0.0

Enhanced: 2.1.0 Addition of Variant 2

**Examples: Variant 1**

```

SELECT
 rid,
 st_value(
 st_mapalgebrafctngb(rast, 1, '32BF', 1, 1, 'st_mean4ma(float[][][],text,text[])':: ↵
 regprocedure, 'ignore', NULL), 2, 2
)
FROM dummy_rast

**9.11.2.5 ST\_Min4ma**

**ST\_Min4ma** — Raster processing function that calculates the minimum pixel value in a neighborhood.

**Synopsis**

float8 **ST\_Min4ma**(float8[][] matrix, text nodatamode, text[] VARIADIC args);  
double precision **ST\_Min4ma**(double precision[][][] value, integer[][] pos, text[] VARIADIC userargs);

**Description**

Calculate the minimum pixel value in a neighborhood of pixels.

For Variant 2, a substitution value for NODATA pixels can be specified by passing that value to userargs.

**Note**

Variant 1 is a specialized callback function for use as a callback parameter to [ST\\_MapAlgebraFctNgb](#).

**Note**

Variant 2 is a specialized callback function for use as a callback parameter to [ST\\_MapAlgebra](#).

**Warning**

Use of Variant 1 is discouraged since [ST\\_MapAlgebraFctNgb](#) has been deprecated as of 2.1.0.

Availability: 2.0.0

Enhanced: 2.1.0 Addition of Variant 2

**Examples**

```
SELECT
 rid,
 st_value(
 st_mapalgebrafctngb(rast, 1, NULL, 1, 1, 'st_min4ma(float[][],text,text[])':: ↵
 regprocedure, 'ignore', NULL), 2, 2

**9.11.2.6 ST\_MinDist4ma**

**ST\_MinDist4ma** — Raster processing function that returns the minimum distance (in number of pixels) between the pixel of interest and a neighboring pixel with value.

**Synopsis**

double precision **ST\_MinDist4ma**(double precision[][][] value, integer[][] pos, text[] VARIADIC userargs);

**Description**

Return the shortest distance (in number of pixels) between the pixel of interest and the closest pixel with value in the neighborhood.

**Note**

The intent of this function is to provide an informative data point that helps infer the usefulness of the pixel of interest's interpolated value from [ST\\_InvDistWeight4ma](#). This function is particularly useful when the neighborhood is sparsely populated.

**Note**

This function is a specialized callback function for use as a callback parameter to [ST\\_MapAlgebra](#).

Availability: 2.1.0

**Examples**

```
-- NEEDS EXAMPLE
```

**See Also**

### 9.11.2.8 ST\_StdDev4ma

`ST_StdDev4ma` — Raster processing function that calculates the standard deviation of pixel values in a neighborhood.

## Synopsis

`float8 ST_StdDev4ma(float8[][] matrix, text nodatamode, text[] VARIADIC args);`  
`double precision ST_StdDev4ma(double precision[][][] value, integer[][] pos, text[] VARIADIC userargs);`

## Description

Calculate the standard deviation of pixel values in a neighborhood of pixels.

### Note

Variant 1 is a specialized callback function for use as a callback parameter to [ST\\_MapAlgebraFctNgb](#).

### Note

Variant 2 is a specialized callback function for use as a callback parameter to [ST\\_MapAlgebra](#).

### Warning

Use of Variant 1 is discouraged since [ST\\_MapAlgebraFctNgb](#) has been deprecated as of 2.1.0.

Availability: 2.0.0

Enhanced: 2.1.0 Addition of Variant 2

## Examples

```
SELECT
 rid,
 st_value(
 st_mapalgebrafctngb(rast, 1, '32BF', 1, 1, 'st_stddev4ma(float[][],text,text[])'::<
 regprocedure, 'ignore', NULL), 2, 2
)

### 9.11.2.9 ST\_Sum4ma

**ST\_Sum4ma** — Raster processing function that calculates the sum of all pixel values in a neighborhood.

## Synopsis

float8 **ST\_Sum4ma**(float8[][] matrix, text nodatamode, text[] VARIADIC args);

double precision **ST\_Sum4ma**(double precision[][][] value, integer[][] pos, text[] VARIADIC userargs);

## Description

Calculate the sum of all pixel values in a neighborhood of pixels.

For Variant 2, a substitution value for NODATA pixels can be specified by passing that value to userargs.

### Note

Variant 1 is a specialized callback function for use as a callback parameter to [ST\\_MapAlgebraFctNgb](#).

### Note

Variant 2 is a specialized callback function for use as a callback parameter to [ST\\_MapAlgebra](#).

### Warning

Use of Variant 1 is discouraged since [ST\\_MapAlgebraFctNgb](#) has been deprecated as of 2.1.0.

Availability: 2.0.0

Enhanced: 2.1.0 Addition of Variant 2

## Examples

```
SELECT
 rid,
 st_value(
 st_mapalgebrafctngb(rast, 1, '32BF', 1, 1, 'st_sum4ma(float[][],text,text[])':: ↵
 regprocedure, 'ignore', NULL), 2, 2
)
FROM dummy_rast
WHERE rid = 2;
 rid | st_value
-----+-----
 2 | 2279
(1 row)
```

## 9.11.3 DEM (Elevation)

### 9.11.3.1 ST\_Aspect

**ST\_Aspect** — Returns the aspect (in degrees by default) of an elevation raster band. Useful for analyzing terrain.

#### Synopsis

raster **ST\_Aspect**(raster rast, integer band=1, text pixeltype=32BF, text units=DEGREES, boolean interpolate\_nodata=FALSE);  
 raster **ST\_Aspect**(raster rast, integer band, raster customextent, text pixeltype=32BF, text units=DEGREES, boolean interpolate\_nodata=FALSE);

#### Description

Returns the aspect (in degrees by default) of an elevation raster band. Utilizes map algebra and applies the aspect equation to neighboring pixels.

`units` indicates the units of the aspect. Possible values are: RADIANS, DEGREES (default).

When `units = RADIANS`, values are between 0 and  $2 * \pi$  radians measured clockwise from North.

When `units = DEGREES`, values are between 0 and 360 degrees measured clockwise from North.

If slope of pixel is zero, aspect of pixel is -1.

#### Note

For more information about Slope, Aspect and Hillshade, please refer to [ESRI - How hillshade works](#) and [ERDAS Field Guide - Aspect Images](#).

Availability: 2.0.0

Enhanced: 2.1.0 Uses `ST_MapAlgebra()` and added optional `interpolate_nodata` function parameter

Changed: 2.1.0 In prior versions, return values were in radians. Now, return values default to degrees

**Examples: Variant 1**

```

WITH foo AS (
 SELECT ST_SetValues(
 ST_AddBand(ST_MakeEmptyRaster(5, 5, 0, 0, 1, -1, 0, 0, 0), 1, '32BF', 0, -9999),
 1, 1, 1, ARRAY[
 [1, 1, 1, 1, 1],

**9.11.3.2 ST\_HillShade**

**ST\_HillShade** — Returns the hypothetical illumination of an elevation raster band using provided azimuth, altitude, brightness and scale inputs.

**Synopsis**

raster **ST\_HillShade**(raster rast, integer band=1, text pixeltype=32BF, double precision azimuth=315, double precision altitude=45, double precision max\_bright=255, double precision scale=1.0, boolean interpolate\_nodata=FALSE);  
 raster **ST\_HillShade**(raster rast, integer band, raster customextent, text pixeltype=32BF, double precision azimuth=315, double precision altitude=45, double precision max\_bright=255, double precision scale=1.0, boolean interpolate\_nodata=FALSE);

**Description**

Returns the hypothetical illumination of an elevation raster band using the azimuth, altitude, brightness, and scale inputs. Utilizes map algebra and applies the hill shade equation to neighboring pixels. Return pixel values are between 0 and 255.

*azimuth* is a value between 0 and 360 degrees measured clockwise from North.

*altitude* is a value between 0 and 90 degrees where 0 degrees is at the horizon and 90 degrees is directly overhead.

*max\_bright* is a value between 0 and 255 with 0 as no brightness and 255 as max brightness.

*scale* is the ratio of vertical units to horizontal. For Feet:LatLon use *scale*=370400, for Meters:LatLon use *scale*=111120.

If *interpolate\_nodata* is TRUE, values for NODATA pixels from the input raster will be interpolated using [ST\\_InvDistWeight4ma](#) before computing the hillshade illumination.

**Note**

For more information about Hillshade, please refer to [How hillshade works](#).

Availability: 2.0.0

Enhanced: 2.1.0 Uses [ST\\_MapAlgebra\(\)](#) and added optional *interpolate\_nodata* function parameter

Changed: 2.1.0 In prior versions, azimuth and altitude were expressed in radians. Now, azimuth and altitude are expressed in degrees

**Examples: Variant 1**

```
WITH foo AS (
 SELECT ST_SetValues(
 ST_AddBand(ST_MakeEmptyRaster(5, 5, 0, 0, 1, -1, 0, 0, 0), 1, '32BF', 0, -9999),

#### 9.11.3.3 ST\_Roughness

**ST\_Roughness** — Returns a raster with the calculated "roughness" of a DEM.

### Synopsis

```
raster ST_Roughness(raster rast, integer nband, raster customextent, text pixeltype="32BF" , boolean interpolate_nodata=FALSE
);
```

**Description**

Calculates the "roughness" of a DEM, by subtracting the maximum from the minimum for a given area.

Availability: 2.1.0

**Examples**

```
-- needs examples
```

**See Also**

[ST\\_MapAlgebra](#), [ST\\_TRI](#), [ST\\_TPI](#), [ST\\_Slope](#), [ST\\_HillShade](#), [ST\\_Aspect](#)

**9.11.3.4 ST\_Slope**

**ST\_Slope** — Returns the slope (in degrees by default) of an elevation raster band. Useful for analyzing terrain.

**Synopsis**

raster **ST\_Slope**(raster rast, integer nband=1, text pixeltype=32BF, text units=DEGREES, double precision scale=1.0, boolean interpolate\_nodata=FALSE);

raster **ST\_Slope**(raster rast, integer nband, raster customextent, text pixeltype=32BF, text units=DEGREES, double precision scale=1.0, boolean interpolate\_nodata=FALSE);

**Description**

Returns the slope (in degrees by default) of an elevation raster band. Utilizes map algebra and applies the slope equation to neighboring pixels.

`units` indicates the units of the slope. Possible values are: RADIANS, DEGREES (default), PERCENT.

`scale` is the ratio of vertical units to horizontal. For Feet:LatLon use `scale=370400`, for Meters:LatLon use `scale=111120`.

If `interpolate_nodata` is TRUE, values for NODATA pixels from the input raster will be interpolated using [ST\\_InvDistWeight4ma](#) before computing the surface slope.

**Note**

For more information about Slope, Aspect and Hillshade, please refer to [ESRI - How hillshade works](#) and [ERDAS Field Guide - Slope Images](#).

Availability: 2.0.0

Enhanced: 2.1.0 Uses `ST_MapAlgebra()` and added optional `units`, `scale`, `interpolate_nodata` function parameters

Changed: 2.1.0 In prior versions, return values were in radians. Now, return values default to degrees

**Examples: Variant 1**

```

#### 9.11.3.5 ST\_TPI

**ST\_TPI** — Returns a raster with the calculated Topographic Position Index.

### Synopsis

raster **ST\_TPI**(raster rast, integer nband, raster customextent, text pixeltype="32BF" , boolean interpolate\_nodata=FALSE );

### Description

Calculates the Topographic Position Index, which is defined as the focal mean with radius of one minus the center cell.

#### Note

This function only supports a focalmean radius of one.

Availability: 2.1.0

### Examples

```
-- needs examples
```

### See Also

[ST\\_MapAlgebra](#), [ST\\_TRI](#), [ST\\_Roughness](#), [ST\\_Slope](#), [ST\\_HillShade](#), [ST\\_Aspect](#)

#### 9.11.3.6 ST\_TRI

**ST\_TRI** — Returns a raster with the calculated Terrain Ruggedness Index.

### Synopsis

raster **ST\_TRI**(raster rast, integer nband, raster customextent, text pixeltype="32BF" , boolean interpolate\_nodata=FALSE );

### Description

Terrain Ruggedness Index is calculated by comparing a central pixel with its neighbors, taking the absolute values of the differences, and averaging the result.

#### Note

This function only supports a focalmean radius of one.

Availability: 2.1.0

## Examples

```
-- needs examples
```

## 9.11.4 Raster to Geometry

### 9.11.4.1 Box3D

Box3D — Returns the box 3d representation of the enclosing box of the raster.

## Synopsis

```
box3d Box3D(raster rast);
```

## Description

Returns the box representing the extent of the raster.

The polygon is defined by the corner points of the bounding box ((MINX, MINY), (MAXX, MAXY))

Changed: 2.0.0 In pre-2.0 versions, there used to be a box2d instead of box3d. Since box2d is a deprecated type, this was changed to box3d.

## Examples

```
SELECT
 rid,
 Box3D(rast) AS rastbox
FROM dummy_rast;
```

```
rid | rastbox
----+-----
1 | BOX3D(0.5 0.5 0,20.5 60.5 0)
2 | BOX3D(3427927.75 5793243.5 0,3427928 5793244 0)
```

## See Also

[ST\\_Envelope](#)

### 9.11.4.2 ST\_ConvexHull

ST\_ConvexHull — Return the convex hull geometry of the raster including pixel values equal to BandNoDataValue. For regular shaped and non-skewed rasters, this gives the same result as ST\_Envelope so only useful for irregularly shaped or skewed rasters.

## Synopsis

```
geometry ST_ConvexHull(raster rast);
```

## Description

Return the convex hull geometry of the raster including the NoDataBandValue band pixels. For regular shaped and non-skewed rasters, this gives more or less the same result as `ST_Envelope` so only useful for irregularly shaped or skewed rasters.

### Note

`ST_Envelope` floors the coordinates and hence add a little buffer around the raster so the answer is subtly different from `ST_ConvexHull` which does not floor.

## Examples

Refer to [PostGIS Raster Specification](#) for a diagram of this.

```
-- Note envelope and convexhull are more or less the same
SELECT ST_AsText(ST_ConvexHull(rast)) As convhull,
 ST_AsText(ST_Envelope(rast)) As env
FROM dummy_rast WHERE rid=1;
```

convhull		env
POLYGON((0.5 0.5,20.5 0.5,20.5 60.5,0.5 60.5,0.5 0.5))		POLYGON((0 0,20 0,20 60,0 60,0 0))

```
-- now we skew the raster
-- note how the convex hull and envelope are now different
SELECT ST_AsText(ST_ConvexHull(rast)) As convhull,
 ST_AsText(ST_Envelope(rast)) As env
FROM (SELECT ST_SetRotation(rast, 0.1, 0.1) As rast
 FROM dummy_rast WHERE rid=1) As foo;
```

convhull		env
POLYGON((0.5 0.5,20.5 1.5,22.5 61.5,2.5 60.5,0.5 0.5))		POLYGON((0 0,22 0,22 61,0 61,0 0))

## See Also

[ST\\_Envelope](#), [ST\\_MinConvexHull](#), [ST\\_ConvexHull](#), [ST\\_AsText](#)

### 9.11.4.3 ST\_DumpAsPolygons

`ST_DumpAsPolygons` — Returns a set of geomval (geom,val) rows, from a given raster band. If no band number is specified, band num defaults to 1.

## Synopsis

```
setof geomval ST_DumpAsPolygons(raster rast, integer band_num=1, boolean exclude_nodata_value=TRUE);
```

## Description

This is a set-returning function (SRF). It returns a set of geomval rows, formed by a geometry (geom) and a pixel band value (val). Each polygon is the union of all pixels for that band that have the same pixel value denoted by val.

ST\_DumpAsPolygon is useful for polygonizing rasters. It is the reverse of a GROUP BY in that it creates new rows. For example it can be used to expand a single raster into multiple POLYGONS/MULTIPOLYGONS.

Availability: Requires GDAL 1.7 or higher.

### Note

If there is a no data value set for a band, pixels with that value will not be returned except in the case of `exclude_nodata_value=false`.

### Note

If you only care about count of pixels with a given value in a raster, it is faster to use [ST\\_ValueCount](#).

### Note

This is different than [ST\\_PixelAsPolygons](#) where one geometry is returned for each pixel regardless of pixel value.

## Examples

```
SELECT val, ST_AsText(geom) As geomwkt
FROM (
SELECT (ST_DumpAsPolygons(rast)).*
FROM dummy_rast
WHERE rid = 2
) As foo
WHERE val BETWEEN 249 and 251
ORDER BY val;
```

val	geomwkt
249	POLYGON((3427927.95 5793243.95,3427927.95 5793243.85,3427928 5793243.85,3427928 5793243.95,3427927.95 5793243.95))
250	POLYGON((3427927.75 5793243.9,3427927.75 5793243.85,3427927.8 5793243.85,3427927.8 5793243.9,3427927.75 5793243.9))
250	POLYGON((3427927.8 5793243.8,3427927.8 5793243.75,3427927.85 5793243.75,3427927.85 5793243.8,3427927.8 5793243.8))
251	POLYGON((3427927.75 5793243.85,3427927.75 5793243.8,3427927.8 5793243.8,3427927.8 5793243.85,3427927.75 5793243.85))

## See Also

[geomval](#), [ST\\_Value](#), [ST\\_Polygon](#), [ST\\_ValueCount](#)

### 9.11.4.4 ST\_Envelope

ST\_Envelope — Returns the polygon representation of the extent of the raster.

**Synopsis**

geometry **ST\_Envelope**(raster rast);

**Description**

Returns the polygon representation of the extent of the raster in spatial coordinate units defined by srid. It is a float8 minimum bounding box represented as a polygon.

The polygon is defined by the corner points of the bounding box ((MINX, MINY), (MINX, MAXY), (MAXX, MAXY), (MAXX, MINY), (MINX, MINY))

**Examples**

```
SELECT rid, ST_AsText(ST_Envelope(rast)) As envgeomwkt
FROM dummy_rast;
```

rid	envgeomwkt
1	POLYGON((0 0,20 0,20 60,0 60,0 0))
2	POLYGON((3427927 5793243,3427928 5793243, 3427928 5793244,3427927 5793244, 3427927 5793243))

**9.11.4.5 ST\_MinConvexHull**

**ST\_MinConvexHull** — Return the convex hull geometry of the raster excluding NODATA pixels.

**Synopsis**

geometry **ST\_MinConvexHull**(raster rast, integer nband=NULL);

**Description**

Return the convex hull geometry of the raster excluding NODATA pixels. If nband is NULL, all bands of the raster are considered.

Availability: 2.1.0

**Examples**

```
WITH foo AS (
 SELECT
 ST_SetValues(
 ST_SetValues(

**9.11.4.6 ST\_Polygon**

ST\_Polygon — Returns a multipolygon geometry formed by the union of pixels that have a pixel value that is not no data value. If no band number is specified, band num defaults to 1.

**Synopsis**

geometry **ST\_Polygon**(raster rast, integer band\_num=1);

**Description**

Availability: 0.1.6 Requires GDAL 1.7 or higher.

Enhanced: 2.1.0 Improved Speed (fully C-Based) and the returning multipolygon is ensured to be valid.

Changed: 2.1.0 In prior versions would sometimes return a polygon, changed to always return multipolygon.

## Examples

```
-- by default no data band value is 0 or not set, so polygon will return a square polygon
SELECT ST_AsText(ST_Polygon(rast)) As geomwkt
FROM dummy_rast
WHERE rid = 2;

geomwkt

MULTIPOLYGON(((3427927.75 5793244,3427928 5793244,3427928 5793243.75,3427927.75 ←
 5793243.75,3427927.75 5793244)))

-- now we change the no data value of first band
UPDATE dummy_rast SET rast = ST_SetBandNoDataValue(rast,1,254)
WHERE rid = 2;
SELECT rid, ST_BandNoDataValue(rast)
from dummy_rast where rid = 2;

-- ST_Polygon excludes the pixel value 254 and returns a multipolygon
SELECT ST_AsText(ST_Polygon(rast)) As geomwkt
FROM dummy_rast
WHERE rid = 2;

geomwkt

MULTIPOLYGON(((3427927.9 5793243.95,3427927.85 5793243.95,3427927.85 5793244,3427927.9 ←
 5793244,3427927.9 5793243.95)),((3427928 5793243.85,3427928 5793243.8,3427927.95 ←

## 9.12 Raster Operators

### 9.12.1 &&

**&&** — Returns TRUE if A's bounding box intersects B's bounding box.

#### Synopsis

```
boolean &&(raster A , raster B);
boolean &&(raster A , geometry B);
boolean &&(geometry B , raster A);
```

#### Description

The **&&** operator returns TRUE if the bounding box of raster/geometr A intersects the bounding box of raster/geometr B.

#### Note

This operand will make use of any indexes that may be available on the rasters.

Availability: 2.0.0

#### Examples

```
SELECT A.rid As a_rid, B.rid As b_rid, A.rast && B.rast As intersect
FROM dummy_rast AS A CROSS JOIN dummy_rast AS B LIMIT 3;
```

a_rid	b_rid	intersect
2	2	t
2	3	f
2	1	f

### 9.12.2 &<

**&<** — Returns TRUE if A's bounding box is to the left of B's.

#### Synopsis

```
boolean &<(raster A , raster B);
```

#### Description

The **&<** operator returns TRUE if the bounding box of raster A overlaps or is to the left of the bounding box of raster B, or more accurately, overlaps or is NOT to the right of the bounding box of raster B.

#### Note

This operand will make use of any indexes that may be available on the rasters.

## Examples

```
SELECT A.rid As a_rid, B.rid As b_rid, A.rast &< B.rast As overleft
FROM dummy_rast AS A CROSS JOIN dummy_rast AS B;
```

a_rid	b_rid	overleft
2	2	t
2	3	f
2	1	f
3	2	t
3	3	t
3	1	f
1	2	t
1	3	t
1	1	t

### 9.12.3 &>

**&>** — Returns TRUE if A's bounding box is to the right of B's.

#### Synopsis

```
boolean &>(raster A , raster B);
```

#### Description

The **&>** operator returns TRUE if the bounding box of raster A overlaps or is to the right of the bounding box of raster B, or more accurately, overlaps or is NOT to the left of the bounding box of raster B.

#### Note

This operand will make use of any indexes that may be available on the geometries.

## Examples

```
SELECT A.rid As a_rid, B.rid As b_rid, A.rast &> B.rast As overright
FROM dummy_rast AS A CROSS JOIN dummy_rast AS B;
```

a_rid	b_rid	overright
2	2	t
2	3	t
2	1	t
3	2	f
3	3	t
3	1	f
1	2	f
1	3	t
1	1	t

### 9.12.4 =

= — Returns `TRUE` if A's bounding box is the same as B's. Uses double precision bounding box.

#### Synopsis

```
boolean =(raster A , raster B);
```

#### Description

The = operator returns `TRUE` if the bounding box of raster A is the same as the bounding box of raster B. PostgreSQL uses the =, <, and > operators defined for rasters to perform internal orderings and comparison of rasters (ie. in a `GROUP BY` or `ORDER BY` clause).

#### Caution

This operand will NOT make use of any indexes that may be available on the rasters. Use `~=` instead. This operator exists mostly so one can group by the raster column.

---

Availability: 2.1.0

#### See Also

`~=`

### 9.12.5 @

@ — Returns `TRUE` if A's bounding box is contained by B's. Uses double precision bounding box.

#### Synopsis

```
boolean @(raster A , raster B);
boolean @(geometry A , raster B);
boolean @(raster B , geometry A);
```

#### Description

The @ operator returns `TRUE` if the bounding box of raster/geometry A is contained by bounding box of raster/geometry B.

#### Note

This operand will use spatial indexes on the rasters.

---

Availability: 2.0.0 raster @ raster, raster @ geometry introduced

Availability: 2.0.5 geometry @ raster introduced

#### See Also

`~`

---

### 9.12.6 ~=

~= — Returns TRUE if A's bounding box is the same as B's.

#### Synopsis

boolean ~= ( raster A , raster B );

#### Description

The ~= operator returns TRUE if the bounding box of raster A is the same as the bounding box of raster B.

#### Note

This operand will make use of any indexes that may be available on the rasters.

Availability: 2.0.0

#### Examples

Very useful usecase is for taking two sets of single band rasters that are of the same chunk but represent different themes and creating a multi-band raster

```
SELECT ST_AddBand(prec.rast, alt.rast) As new_rast
FROM prec INNER JOIN alt ON (prec.rast ~= alt.rast);
```

#### See Also

[ST\\_AddBand](#), [=](#)

### 9.12.7 ~

~ — Returns TRUE if A's bounding box is contains B's. Uses double precision bounding box.

#### Synopsis

boolean ~( raster A , raster B );  
boolean ~( geometry A , raster B );  
boolean ~( raster B , geometry A );

#### Description

The ~ operator returns TRUE if the bounding box of raster/geometry A is contains bounding box of raster/geometr B.

#### Note

This operand will use spatial indexes on the rasters.

Availability: 2.0.0

**See Also**[@](#)

## 9.13 Raster and Raster Band Spatial Relationships

### 9.13.1 ST\_Contains

**ST\_Contains** — Return true if no points of raster *rastB* lie in the exterior of raster *rastA* and at least one point of the interior of *rastB* lies in the interior of *rastA*.

**Synopsis**

boolean **ST\_Contains**( raster *rastA* , integer *nbandA* , raster *rastB* , integer *nbandB* );  
 boolean **ST\_Contains**( raster *rastA* , raster *rastB* );

**Description**

Raster *rastA* contains *rastB* if and only if no points of *rastB* lie in the exterior of *rastA* and at least one point of the interior of *rastB* lies in the interior of *rastA*. If the band number is not provided (or set to NULL), only the convex hull of the raster is considered in the test. If the band number is provided, only those pixels with value (not NODATA) are considered in the test.

**Note**

This function will make use of any indexes that may be available on the rasters.

**Note**

To test the spatial relationship of a raster and a geometry, use **ST\_Polygon** on the raster, e.g. **ST\_Contains(ST\_Polygon(raster), geometry)** or **ST\_Contains(geometry, ST\_Polygon(raster))**.

**Note**

**ST\_Contains()** is the inverse of **ST\_Within()**. So, **ST\_Contains(rastA, rastB)** implies **ST\_Within(rastB, rastA)**.

Availability: 2.1.0

**Examples**

```
-- specified band numbers
SELECT r1.rid, r2.rid, ST_Contains(r1.rast, 1, r2.rast, 1) FROM dummy_rast r1 CROSS JOIN ↔
 dummy_rast r2 WHERE r1.rid = 1;
```

NOTICE: The first raster provided has no bands

```
rid | rid | st_contains
-----+-----
 1 | 1 |
 1 | 2 | f
```

```
-- no band numbers specified
SELECT r1.rid, r2.rid, ST_Contains(r1.rast, r2.rast) FROM dummy_rast r1 CROSS JOIN ↵
 dummy_rast r2 WHERE r1.rid = 1;
rid | rid | st_contains
-----+-----+-----
 1 | 1 | t
 1 | 2 | f
```

### See Also

[ST\\_Intersects](#), [ST\\_Within](#)

### 9.13.2 ST\_ContainsProperly

`ST_ContainsProperly` — Return true if `rastB` intersects the interior of `rastA` but not the boundary or exterior of `rastA`.

#### Synopsis

```
boolean ST_ContainsProperly(raster rastA , integer nbandA , raster rastB , integer nbandB);
boolean ST_ContainsProperly(raster rastA , raster rastB);
```

#### Description

Raster `rastA` contains properly `rastB` if `rastB` intersects the interior of `rastA` but not the boundary or exterior of `rastA`. If the band number is not provided (or set to `NULL`), only the convex hull of the raster is considered in the test. If the band number is provided, only those pixels with value (not `NODATA`) are considered in the test.

Raster `rastA` does not contain properly itself but does contain itself.

#### Note

This function will make use of any indexes that may be available on the rasters.

#### Note

To test the spatial relationship of a raster and a geometry, use `ST_Polygon` on the raster, e.g. `ST_ContainsProperly(ST_Polygon(raster), geometry)` or `ST_ContainsProperly(geometry, ST_Polygon(raster))`.

Availability: 2.1.0

#### Examples

```
SELECT r1.rid, r2.rid, ST_ContainsProperly(r1.rast, 1, r2.rast, 1) FROM dummy_rast r1 CROSS ↵
 JOIN dummy_rast r2 WHERE r1.rid = 2;

rid | rid | st_containsproperly
-----+-----+-----
 2 | 1 | f
 2 | 2 | f
```

**See Also**

[ST\\_Intersects](#), [ST\\_Contains](#)

**9.13.3 ST\_Covers**

`ST_Covers` — Return true if no points of raster `rastB` lie outside raster `rastA`.

**Synopsis**

```
boolean ST_Covers(raster rastA , integer nbandA , raster rastB , integer nbandB);
boolean ST_Covers(raster rastA , raster rastB);
```

**Description**

Raster `rastA` covers `rastB` if and only if no points of `rastB` lie in the exterior of `rastA`. If the band number is not provided (or set to `NULL`), only the convex hull of the raster is considered in the test. If the band number is provided, only those pixels with value (not `NODATA`) are considered in the test.

**Note**

This function will make use of any indexes that may be available on the rasters.

**Note**

To test the spatial relationship of a raster and a geometry, use `ST_Polygon` on the raster, e.g. `ST_Covers(ST_Polygon(raster), geometry)` or `ST_Covers(geometry, ST_Polygon(raster))`.

Availability: 2.1.0

**Examples**

```
SELECT r1.rid, r2.rid, ST_Covers(r1.rast, 1, r2.rast, 1) FROM dummy_rast r1 CROSS JOIN ↔
dummy_rast r2 WHERE r1.rid = 2;
```

```
rid | rid | st_covers
----+----+-----
 2 | 1 | f
 2 | 2 | t
```

**See Also**

[ST\\_Intersects](#), [ST\\_CoveredBy](#)

**9.13.4 ST\_CoveredBy**

`ST_CoveredBy` — Return true if no points of raster `rastA` lie outside raster `rastB`.

## Synopsis

boolean **ST\_CoveredBy**( raster rastA , integer nbandA , raster rastB , integer nbandB );  
 boolean **ST\_CoveredBy**( raster rastA , raster rastB );

## Description

Raster rastA is covered by rastB if and only if no points of rastA lie in the exterior of rastB. If the band number is not provided (or set to NULL), only the convex hull of the raster is considered in the test. If the band number is provided, only those pixels with value (not NODATA) are considered in the test.

### Note

This function will make use of any indexes that may be available on the rasters.

### Note

To test the spatial relationship of a raster and a geometry, use `ST_Polygon` on the raster, e.g. `ST_CoveredBy(ST_Polygon(raster), geometry)` or `ST_CoveredBy(geometry, ST_Polygon(raster))`.

Availability: 2.1.0

## Examples

```
SELECT r1.rid, r2.rid, ST_CoveredBy(r1.rast, 1, r2.rast, 1) FROM dummy_rast r1 CROSS JOIN ↵
 dummy_rast r2 WHERE r1.rid = 2;
```

rid	rid	st_coveredby
2	1	f
2	2	t

## See Also

[ST\\_Intersects](#), [ST\\_Covers](#)

### 9.13.5 ST\_Disjoint

`ST_Disjoint` — Return true if raster rastA does not spatially intersect rastB.

## Synopsis

boolean **ST\_Disjoint**( raster rastA , integer nbandA , raster rastB , integer nbandB );  
 boolean **ST\_Disjoint**( raster rastA , raster rastB );

## Description

Raster `rastA` and `rastB` are disjointed if they do not share any space together. If the band number is not provided (or set to `NULL`), only the convex hull of the raster is considered in the test. If the band number is provided, only those pixels with value (not `NODATA`) are considered in the test.

### Note

This function does NOT use any indexes.

### Note

To test the spatial relationship of a raster and a geometry, use `ST_Polygon` on the raster, e.g. `ST_Disjoint(ST_Polygon(raster), geometry)`.

Availability: 2.1.0

## Examples

```
-- rid = 1 has no bands, hence the NOTICE and the NULL value for st_disjoint
SELECT r1.rid, r2.rid, ST_Disjoint(r1.rast, 1, r2.rast, 1) FROM dummy_rast r1 CROSS JOIN ↵
 dummy_rast r2 WHERE r1.rid = 2;
```

NOTICE: The second raster provided has no bands

```
rid | rid | st_disjoint
-----+-----+-----
 2 | 1 |
 2 | 2 | f
```

```
-- this time, without specifying band numbers
```

```
SELECT r1.rid, r2.rid, ST_Disjoint(r1.rast, r2.rast) FROM dummy_rast r1 CROSS JOIN ↵
 dummy_rast r2 WHERE r1.rid = 2;
```

```
rid | rid | st_disjoint
-----+-----+-----
 2 | 1 | t
 2 | 2 | f
```

## See Also

[ST\\_Intersects](#)

### 9.13.6 ST\_Intersects

`ST_Intersects` — Return true if raster `rastA` spatially intersects raster `rastB`.

## Synopsis

```
boolean ST_Intersects(raster rastA , integer nbandA , raster rastB , integer nbandB);
boolean ST_Intersects(raster rastA , raster rastB);
boolean ST_Intersects(raster rast , integer nband , geometry geommin);
boolean ST_Intersects(raster rast , geometry geommin , integer nband=NULL);
boolean ST_Intersects(geometry geommin , raster rast , integer nband=NULL);
```

## Description

Return true if raster *rastA* spatially intersects raster *rastB*. If the band number is not provided (or set to `NULL`), only the convex hull of the raster is considered in the test. If the band number is provided, only those pixels with value (not `NODATA`) are considered in the test.

### Note

This function will make use of any indexes that may be available on the rasters.

Enhanced: 2.0.0 support raster/raster intersects was introduced.

### Warning

Changed: 2.1.0 The behavior of the `ST_Intersects(raster, geometry)` variants changed to match that of `ST_Intersects(geometry, raster)`.

## Examples

```
-- different bands of same raster
SELECT ST_Intersects(rast, 2, rast, 3) FROM dummy_rast WHERE rid = 2;

st_intersects

t
```

## See Also

[ST\\_Intersection](#), [ST\\_Disjoint](#)

## 9.13.7 ST\_Overlaps

`ST_Overlaps` — Return true if raster *rastA* and *rastB* intersect but one does not completely contain the other.

### Synopsis

```
boolean ST_Overlaps(raster rastA , integer nbandA , raster rastB , integer nbandB);
boolean ST_Overlaps(raster rastA , raster rastB);
```

### Description

Return true if raster *rastA* spatially overlaps raster *rastB*. This means that *rastA* and *rastB* intersect but one does not completely contain the other. If the band number is not provided (or set to `NULL`), only the convex hull of the raster is considered in the test. If the band number is provided, only those pixels with value (not `NODATA`) are considered in the test.

### Note

This function will make use of any indexes that may be available on the rasters.

**Note**

To test the spatial relationship of a raster and a geometry, use `ST_Polygon` on the raster, e.g. `ST_Overlaps(ST_Polygon(raster), geometry)`.

Availability: 2.1.0

**Examples**

```
-- comparing different bands of same raster
SELECT ST_Overlaps(rast, 1, rast, 2) FROM dummy_rast WHERE rid = 2;

st_overlaps

f
```

**See Also**

[ST\\_Intersects](#)

**9.13.8 ST\_Touches**

`ST_Touches` — Return true if raster `rastA` and `rastB` have at least one point in common but their interiors do not intersect.

**Synopsis**

boolean **ST\_Touches**( raster `rastA` , integer `nbandA` , raster `rastB` , integer `nbandB` );  
 boolean **ST\_Touches**( raster `rastA` , raster `rastB` );

**Description**

Return true if raster `rastA` spatially touches raster `rastB`. This means that `rastA` and `rastB` have at least one point in common but their interiors do not intersect. If the band number is not provided (or set to `NULL`), only the convex hull of the raster is considered in the test. If the band number is provided, only those pixels with value (not `NODATA`) are considered in the test.

**Note**

This function will make use of any indexes that may be available on the rasters.

**Note**

To test the spatial relationship of a raster and a geometry, use `ST_Polygon` on the raster, e.g. `ST_Touches(ST_Polygon(raster), geometry)`.

Availability: 2.1.0

## Examples

```
SELECT r1.rid, r2.rid, ST_Touches(r1.rast, 1, r2.rast, 1) FROM dummy_rast r1 CROSS JOIN ←
 dummy_rast r2 WHERE r1.rid = 2;
```

```
rid | rid | st_touches
-----+-----+-----
 2 | 1 | f
 2 | 2 | f
```

## See Also

[ST\\_Intersects](#)

## 9.13.9 ST\_SameAlignment

**ST\_SameAlignment** — Returns true if rasters have same skew, scale, spatial ref, and offset (pixels can be put on same grid without cutting into pixels) and false if they don't with notice detailing issue.

### Synopsis

```
boolean ST_SameAlignment(raster rastA , raster rastB);
boolean ST_SameAlignment(double precision ulx1 , double precision uly1 , double precision scalex1 , double precision scaley1
, double precision skewx1 , double precision skewy1 , double precision ulx2 , double precision uly2 , double precision scalex2 ,
double precision scaley2 , double precision skewx2 , double precision skewy2);
boolean ST_SameAlignment(raster set rastfield);
```

### Description

Non-Aggregate version (Variants 1 and 2): Returns true if the two rasters (either provided directly or made using the values for upperleft, scale, skew and srid) have the same scale, skew, srid and at least one of any of the four corners of any pixel of one raster falls on any corner of the grid of the other raster. Returns false if they don't and a NOTICE detailing the alignment issue.

Aggregate version (Variant 3): From a set of rasters, returns true if all rasters in the set are aligned. The **ST\_SameAlignment()** function is an "aggregate" function in the terminology of PostgreSQL. That means that it operates on rows of data, in the same way the **SUM()** and **AVG()** functions do.

Availability: 2.0.0

Enhanced: 2.1.0 addition of Aggregate variant

### Examples: Rasters

```
SELECT ST_SameAlignment(
 ST_MakeEmptyRaster(1, 1, 0, 0, 1, 1, 0, 0),
 ST_MakeEmptyRaster(1, 1, 0, 0, 1, 1, 0, 0)
) as sm;
```

```
sm

t
```

```
SELECT ST_SameAlignment(A.rast,b.rast)
FROM dummy_rast AS A CROSS JOIN dummy_rast AS B;

NOTICE: The two rasters provided have different SRIDs
NOTICE: The two rasters provided have different SRIDs

f
f
```

### See Also

Section 5.1, [ST\\_NotSameAlignmentReason](#), [ST\\_MakeEmptyRaster](#)

### 9.13.10 ST\_NotSameAlignmentReason

`ST_NotSameAlignmentReason` — Returns text stating if rasters are aligned and if not aligned, a reason why.

#### Synopsis

text `ST_NotSameAlignmentReason`(raster rastA, raster rastB);

#### Description

Returns text stating if rasters are aligned and if not aligned, a reason why.

#### Note

If there are several reasons why the rasters are not aligned, only one reason (the first test to fail) will be returned.

Availability: 2.1.0

#### Examples

```
SELECT
 ST_SameAlignment (
 ST_MakeEmptyRaster(1, 1, 0, 0, 1, 1, 0, 0),
 ST_MakeEmptyRaster(1, 1, 0, 0, 1.1, 1.1, 0, 0)
),
 ST_NotSameAlignmentReason(
 ST_MakeEmptyRaster(1, 1, 0, 0, 1, 1, 0, 0),
 ST_MakeEmptyRaster(1, 1, 0, 0, 1.1, 1.1, 0, 0)
)
;

 st_samealignment | st_otsamealignmentreason
-----+-----
f | The rasters have different scales on the X axis
(1 row)
```

**See Also**

Section [5.1](#), [ST\\_SameAlignment](#)

**9.13.11 ST\_Within**

**ST\_Within** — Return true if no points of raster *rastA* lie in the exterior of raster *rastB* and at least one point of the interior of *rastA* lies in the interior of *rastB*.

**Synopsis**

```
boolean ST_Within(raster rastA , integer nbandA , raster rastB , integer nbandB);
boolean ST_Within(raster rastA , raster rastB);
```

**Description**

Raster *rastA* is within *rastB* if and only if no points of *rastA* lie in the exterior of *rastB* and at least one point of the interior of *rastA* lies in the interior of *rastB*. If the band number is not provided (or set to NULL), only the convex hull of the raster is considered in the test. If the band number is provided, only those pixels with value (not NODATA) are considered in the test.

**Note**

This operand will make use of any indexes that may be available on the rasters.

**Note**

To test the spatial relationship of a raster and a geometry, use `ST_Polygon` on the raster, e.g. `ST_Within(ST_Polygon(raster), geometry)` or `ST_Within(geometry, ST_Polygon(raster))`.

**Note**

`ST_Within()` is the inverse of `ST_Contains()`. So, `ST_Within(rastA, rastB)` implies `ST_Contains(rastB, rastA)`.

Availability: 2.1.0

**Examples**

```
SELECT r1.rid, r2.rid, ST_Within(r1.rast, 1, r2.rast, 1) FROM dummy_rast r1 CROSS JOIN ↔
dummy_rast r2 WHERE r1.rid = 2;
```

```
rid | rid | st_within
-----+-----+-----
 2 | 1 | f
 2 | 2 | t
```

**See Also**

[ST\\_Intersects](#), [ST\\_Contains](#), [ST\\_DWithin](#), [ST\\_DFullyWithin](#)

### 9.13.12 ST\_DWithin

ST\_DWithin — Return true if rasters rastA and rastB are within the specified distance of each other.

#### Synopsis

```
boolean ST_DWithin(raster rastA , integer nbandA , raster rastB , integer nbandB , double precision distance_of_srid);
boolean ST_DWithin(raster rastA , raster rastB , double precision distance_of_srid);
```

#### Description

Return true if rasters rastA and rastB are within the specified distance of each other. If the band number is not provided (or set to NULL), only the convex hull of the raster is considered in the test. If the band number is provided, only those pixels with value (not NODATA) are considered in the test.

The distance is specified in units defined by the spatial reference system of the rasters. For this function to make sense, the source rasters must both be of the same coordinate projection, having the same SRID.

#### Note

This operand will make use of any indexes that may be available on the rasters.

#### Note

To test the spatial relationship of a raster and a geometry, use ST\_Polygon on the raster, e.g. ST\_DWithin(ST\_Polygon(raster), geometry).

Availability: 2.1.0

#### Examples

```
SELECT r1.rid, r2.rid, ST_DWithin(r1.rast, 1, r2.rast, 1, 3.14) FROM dummy_rast r1 CROSS JOIN dummy_rast r2 WHERE r1.rid = 2;
```

rid	rid	st_dwithin
2	1	f
2	2	t

#### See Also

[ST\\_Within](#), [ST\\_DFullyWithin](#)

### 9.13.13 ST\_DFullyWithin

ST\_DFullyWithin — Return true if rasters rastA and rastB are fully within the specified distance of each other.

#### Synopsis

```
boolean ST_DFullyWithin(raster rastA , integer nbandA , raster rastB , integer nbandB , double precision distance_of_srid);
boolean ST_DFullyWithin(raster rastA , raster rastB , double precision distance_of_srid);
```

## Description

Return true if rasters `rastA` and `rastB` are fully within the specified distance of each other. If the band number is not provided (or set to `NULL`), only the convex hull of the raster is considered in the test. If the band number is provided, only those pixels with value (not `NODATA`) are considered in the test.

The distance is specified in units defined by the spatial reference system of the rasters. For this function to make sense, the source rasters must both be of the same coordinate projection, having the same `SRID`.

### Note

This operand will make use of any indexes that may be available on the rasters.

### Note

To test the spatial relationship of a raster and a geometry, use `ST_Polygon` on the raster, e.g. `ST_DFullyWithin(ST_Polygon(raster), geometry)`.

Availability: 2.1.0

## Examples

```
SELECT r1.rid, r2.rid, ST_DFullyWithin(r1.rast, 1, r2.rast, 1, 3.14) FROM dummy_rast r1 ↔
CROSS JOIN dummy_rast r2 WHERE r1.rid = 2;
```

rid	rid	st_dfullywithin
2	1	f
2	2	t

## Chapter 10

# PostGIS Raster Frequently Asked Questions

1. *I'm getting error `ERROR:RASTER_fromGDALRaster:Could not open bytea with GDAL.Check that the bytea is of a GDAL supported format. when using ST_FromGDALRaster or ERROR:rt_raster_to_gdal:Could not load the output GDAL driver when trying to use ST_AsPNG or other raster input functions.`*

As of PostGIS 2.1.3 and 2.0.5, a security change was made to by default disable all GDAL drivers and out of db rasters. The release notes are at [PostGIS 2.0.6, 2.1.3 security release](#). In order to reenale specific drivers or all drivers and reenale out of database support, refer to Section [2.1](#).

2. *Where can I find out more about the PostGIS Raster Project?*

Refer to the [PostGIS Raster home page](#).

3. *Are there any books or tutorials to get me started with this wonderful invention?*

There is a full length beginner tutorial [Intersecting vector buffers with large raster coverage using PostGIS Raster](#). Jorge has a series of blog articles on PostGIS Raster that demonstrate how to load raster data as well as cross compare to same tasks in Oracle GeoRaster. Check out [Jorge's PostGIS Raster / Oracle GeoRaster Series](#). There is a whole chapter (more than 35 pages of content) dedicated to PostGIS Raster with free code and data downloads at [PostGIS in Action - Raster chapter](#). You can [buy PostGIS in Action](#) now from Manning in hard-copy (significant discounts for bulk purchases) or just the E-book format. You can also buy from Amazon and various other book distributors. All hard-copy books come with a free coupon to download the E-book version. Here is a review from a PostGIS Raster user [PostGIS raster applied to land classification urban forestry](#)

4. *How do I install Raster support in my PostGIS database?*

The easiest is to download binaries for PostGIS and Raster which are currently available for windows and latest versions of Mac OSX. First you need a working PostGIS 2.0.0 or above and be running PostgreSQL 8.4, 9.0, or 9.1. Note in PostGIS 2.0 PostGIS Raster is fully integrated, so it will be compiled when you compile PostGIS. Instructions for installing and running under windows are available at [How to Install and Configure PostGIS raster on windows](#) If you are on windows, you can compile yourself, or use the [pre-compiled PostGIS Raster windows binaries](#). If you are on Mac OSX Leopard or Snow Leopard, there are binaries available at [Kyng Chaos Mac OSX PostgreSQL/GIS binaries](#). Then to enable raster support in your database, run the `rtpostgis.sql` file in your database. To upgrade an existing install use `rtpostgis_upgrade_minor.sql` instead of `rtpostgis.sql` For other platforms, you generally need to compile yourself. Dependencies are PostGIS and GDAL. For more details about compiling from source, please refer to [Installing PostGIS Raster from source \(in prior versions of PostGIS\)](#)

5. *I get error could not load library "C:/Program Files/PostgreSQL/8.4/lib/rtpostgis.dll": The specified module could not be found. or could not load library on Linux when trying to run rtpostgis.sql*

`rtpostgis.so/dll` is built with dependency on `libgdal.dll/so`. Make sure for Windows you have `libgdal-1.dll` in the bin folder of your PostgreSQL install. For Linux `libgdal` has to be in your path or bin folder. You may also run into different errors if you don't have PostGIS installed in your database. Make sure to install PostGIS first in your database before trying to install the raster support.

## 6. How do I load Raster data into PostGIS?

The latest version of PostGIS comes packaged with a `raster2pgsql` raster loader executable capable of loading many kinds of rasters and also generating lower resolution overviews without any additional software. Please refer to Section 5.1.1 for more details. Pre-2.0 versions came with a `raster2pgsql.py` that required python with numpy and GDAL. This is no longer needed.

## 7. What kind of raster file formats can I load into my database?

Any that your GDAL library supports. GDAL supported formats are documented [GDAL File Formats](#). Your particular GDAL install may not support all formats. To verify the ones supported by your particular GDAL install, you can use

```
raster2pgsql -G
```

## 8. Can I export my PostGIS raster data to other raster formats?

Yes GDAL 1.7+ has a PostGIS raster driver, but is only compiled in if you choose to compile with PostgreSQL support. The driver currently doesn't support irregularly blocked rasters, although you can store irregularly blocked rasters in PostGIS raster data type. If you are compiling from source, you need to include in your configure

```
--with-pg=path/to/pg_config
```

to enable the driver. Refer to [GDAL Build Hints](#) for tips on building GDAL against in various OS platforms. If your version of GDAL is compiled with the PostGIS Raster driver you should see PostGIS Raster in list when you do

```
gdalinfo --formats
```

To get a summary about your raster via GDAL use `gdalinfo`:

```
gdalinfo "PG:host=localhost port=5432 dbname='mygisdb' user='postgres' password=' ←
whatever' schema='someschema' table=sometable"
```

To export data to other raster formats, use `gdal_translate` the below will export all data from a table to a PNG file at 10% size. Depending on your pixel band types, some translations may not work if the export format does not support that Pixel type. For example floating point band types and 32 bit unsigned ints will not translate easily to JPG or some others. Here is an example simple translation

```
gdal_translate -of PNG -outsize 10% 10% "PG:host=localhost port=5432 dbname='mygisdb' ←
user='postgres' password='whatever' schema='someschema' table=sometable" C:\ ←
somefile.png
```

You can also use SQL where clauses in your export using the `where=...` in your driver connection string. Below are some using a where clause

```
gdal_translate -of PNG -outsize 10% 10% "PG:host=localhost port=5432 dbname='mygisdb' ←
user='postgres' password='whatever' schema='someschema' table=sometable where=' ←
filename='abcd.sid'" " C:\somefile.png
```

```
gdal_translate -of PNG -outsize 10% 10% "PG:host=localhost port=5432 dbname='mygisdb' ←
user='postgres' password='whatever' schema='someschema' table=sometable where=' ←
ST_Intersects(rast, ST_SetSRID(ST_Point(-71.032,42.3793),4326))' " C:\ ←
intersectregion.png
```

To see more examples and syntax refer to [Reading Raster Data of PostGIS Raster section](#)

## 9. Are their binaries of GDAL available already compiled with PostGIS Raster support?

Yes. Check out the page [GDAL Binaries](#) page. Any compiled with PostgreSQL support should have PostGIS Raster in them. PostGIS Raster is undergoing many changes. If you want to get the latest nightly build for Windows -- then check out the Tamas Szekeres nightly builds built with Visual Studio which contain GDAL trunk, Python Bindings and MapServer executables and PostGIS Raster driver built-in. Just click the SDK bat and run your commands from there. <http://www.gisinternals.com>. Also available are VS project files. [FWTools latest stable version for Windows is compiled with Raster support](#).

#### 10. What tools can I use to view PostGIS raster data?

You can use MapServer compiled with GDAL 1.7+ and PostGIS Raster driver support to view Raster data. QuantumGIS (QGIS) now supports viewing of PostGIS Raster if you have PostGIS raster driver installed. In theory any tool that renders data using GDAL can support PostGIS raster data or support it with fairly minimal effort. Again for Windows, Tamas' binaries <http://www.gisinternals.com> are a good choice if you don't want the hassle of having to setup to compile your own.

#### 11. How can I add a PostGIS raster layer to my MapServer map?

First you need GDAL 1.7 or higher compiled with PostGIS raster support. GDAL 1.8 or above is preferred since many issues have been fixed in 1.8 and more PostGIS raster issues fixed in trunk version. You can much like you can with any other raster. Refer to [MapServer Raster processing options](#) for list of various processing functions you can use with MapServer raster layers. What makes PostGIS raster data particularly interesting, is that since each tile can have various standard database columns, you can segment it in your data source. Below is an example of how you would define a PostGIS raster layer in MapServer.

#### Note

The mode=2 is required for tiled rasters and was added in PostGIS 2.0 and GDAL 1.8 drivers. This does not exist in GDAL 1.7 drivers.

```
-- displaying raster with standard raster options
LAYER
 NAME coolwktraster
 TYPE raster
 STATUS ON
 DATA "PG:host=localhost port=5432 dbname='somedb' user='someuser' password='whatever'
 schema='someschema' table='cooltable' mode='2'"
 PROCESSING "NODATA=0"
 PROCESSING "SCALE=AUTO"
 #... other standard raster processing functions here
 #... classes are optional but useful for 1 band data
 CLASS
 NAME "boring"
 EXPRESSION ([pixel] < 20)
 COLOR 250 250 250
 END
 CLASS
 NAME "mildly interesting"
 EXPRESSION ([pixel] > 20 AND [pixel] < 1000)
 COLOR 255 0 0
 END
 CLASS
 NAME "very interesting"
 EXPRESSION ([pixel] >= 1000)
 COLOR 0 255 0
 END
END
```

```
-- displaying raster with standard raster options and a where clause
LAYER
 NAME soil_survey2009
 TYPE raster
 STATUS ON
 DATA "PG:host=localhost port=5432 dbname='somedb' user='someuser' password='whatever'
 schema='someschema' table='cooltable' where='survey_year=2009' mode='2'"
 PROCESSING "NODATA=0"
 #... other standard raster processing functions here
 #... classes are optional but useful for 1 band data
END
```

12. *What functions can I currently use with my raster data?*

Refer to the list of Chapter 9. There are more, but this is still a work in progress. Refer to the [PostGIS Raster roadmap page](#) for details of what you can expect in the future.

13. *I am getting error ERROR: function st\_intersects(raster, unknown) is not unique or st\_union(geometry,text) is not unique. How do I fix?*

The function is not unique error happens if one of your arguments is a textual representation of a geometry instead of a geometry. In these cases, PostgreSQL marks the textual representation as an unknown type, which means it can fall into the `st_intersects(raster, geometry)` or `st_intersects(raster,raster)` thus resulting in a non-unique case since both functions can in theory support your request. To prevent this, you need to cast the textual representation of the geometry to a geometry. For example if your code looks like this:

```
SELECT rast
FROM my_raster
WHERE ST_Intersects(rast, 'SRID=4326;POINT(-10 10)');
```

Cast the textual geometry representation to a geometry by changing your code to this:

```
SELECT rast
FROM my_raster
WHERE ST_Intersects(rast, 'SRID=4326;POINT(-10 10)::geometry');
```

14. *How is PostGIS Raster different from Oracle GeoRaster (SDO\_GEORASTER) and SDO\_RASTER types?*

For a more extensive discussion on this topic, check out Jorge Arévalo [Oracle GeoRaster and PostGIS Raster: First impressions](#). The major advantage of one-georeference-by-raster over one-georeference-by-layer is to allow: \* coverages to be not necessarily rectangular (which is often the case of raster coverage covering large extents. See the possible raster arrangements in the documentation) \* rasters to overlaps (which is necessary to implement lossless vector to raster conversion) These arrangements are possible in Oracle as well, but they imply the storage of multiple SDO\_GEORASTER objects linked to as many SDO\_RASTER tables. A complex coverage can lead to hundreds of tables in the database. With PostGIS Raster you can store a similar raster arrangement into a unique table. It's a bit like if PostGIS would force you to store only full rectangular vector coverage without gaps or overlaps (a perfect rectangular topological layer). This is very practical in some applications but practice has shown that it is not realistic or desirable for most geographical coverages. Vector structures needs the flexibility to store discontinuous and non-rectangular coverages. We think it is a big advantage that raster structure should benefit as well.

15. *raster2pgsql load of large file fails with String of N bytes is too long for encoding conversion?*

`raster2pgsql` doesn't make any connections to your database when generating the file to load. If your database has set an explicit client encoding different from your database encoding, then when loading large raster files (above 30 MB in size), you may run into a `bytes is too long for encoding conversion`. This generally happens if for example you have your database in UTF8, but to support windows apps, you have the client encoding set to WIN1252. To work around this make sure the client encoding is the same as your database encoding during load. You can do this by explicitly setting the encoding in your load script. Example, if you are on windows:

```
set PGCLIENTENCODING=UTF8
```

If you are on Unix/Linux

```
export PGCLIENTENCODING=UTF8
```

More details of this issue are detailed in <http://trac.osgeo.org/postgis/ticket/2209>

## Chapter 11

# Topology

The PostGIS Topology types and functions are used to manage topological objects such as faces, edges and nodes.

Sandro Santilli's presentation at PostGIS Day Paris 2011 conference gives a good synopsis of PostGIS Topology and where it is headed [Topology with PostGIS 2.0 slide deck](#).

Vincent Picavet provides a good synopsis and overview of what is Topology, how is it used, and various FOSS4G tools that support it in [PostGIS Topology PGConf EU 2012](#).

An example of a topologically based GIS database is the [US Census Topologically Integrated Geographic Encoding and Referencing System \(TIGER\)](#) database. If you want to experiment with PostGIS topology and need some data, check out [Topology\\_Load\\_Tiger](#).

The PostGIS topology module has existed in prior versions of PostGIS but was never part of the Official PostGIS documentation. In PostGIS 2.0.0 major cleanup is going on to remove use of all deprecated functions in it, fix known usability issues, better document the features and functions, add new functions, and enhance to closer conform to SQL-MM standards.

Details of this project can be found at [PostGIS Topology Wiki](#)

All functions and tables associated with this module are installed in a schema called `topology`.

Functions that are defined in SQL/MM standard are prefixed with `ST_` and functions specific to PostGIS are not prefixed.

To build PostGIS 2.0 with topology support, compile with the `--with-topology` option as described in [Chapter 2](#). Some functions depend on GEOS 3.3+ so you should compile with GEOS 3.3+ to fully utilize the topology support.

### 11.1 Topology Types

#### 11.1.1 `getfaceedges_returntype`

`getfaceedges_returntype` — A composite type that consists of a sequence number and edge number. This is the return type for `ST_GetFaceEdges`

##### Description

A composite type that consists of a sequence number and edge number. This is the return type for `ST_GetFaceEdges` function.

1. `sequence` is an integer: Refers to a topology defined in the `topology.topology` table which defines the topology schema and `srid`.
  2. `edge` is an integer: The identifier of an edge.
-

## 11.1.2 TopoGeometry

TopoGeometry — A composite type representing a topologically defined geometry

### Description

A composite type that refers to a topology geometry in a specific topology layer, having a specific type and a specific id. The elements of a TopoGeometry are the properties: `topology_id`, `layer_id`, `id` integer, `type` integer.

1. `topology_id` is an integer: Refers to a topology defined in the `topology.topology` table which defines the topology schema and `srid`.
2. `layer_id` is an integer: The `layer_id` in the `layers` table that the TopoGeometry belongs to. The combination of `topology_id`, `layer_id` provides a unique reference in the `topology.layers` table.
3. `id` is an integer: The `id` is the autogenerated sequence number that uniquely defines the topogeometry in the respective topology layer.
4. `type` integer between 1 - 4 that defines the geometry type: 1:[multi]point, 2:[multi]line, 3:[multi]poly, 4:collection

### Casting Behavior

This section lists the automatic as well as explicit casts allowed for this data type

Cast To	Behavior
geometry	automatic

### See Also

[CreateTopoGeom](#)

## 11.1.3 validatetopology\_returntype

`validatetopology_returntype` — A composite type that consists of an error message and `id1` and `id2` to denote location of error. This is the return type for `ValidateTopology`

### Description

A composite type that consists of an error message and two integers. The `ValidateTopology` function returns a set of these to denote validation errors and the `id1` and `id2` to denote the ids of the topology objects involved in the error.

1. `error` is varchar: Denotes type of error.  
Current error descriptors are: coincident nodes, edge crosses node, edge not simple, edge end node geometry mis-match, edge start node geometry mismatch, face overlaps face, face within face,
2. `id1` is an integer: Denotes identifier of edge / face / nodes in error.
3. `id2` is an integer: For errors that involve 2 objects denotes the secondary edge / or node

### See Also

[ValidateTopology](#)

## 11.2 Topology Domains

### 11.2.1 TopoElement

TopoElement — An array of 2 integers generally used to identify a TopoGeometry component.

#### Description

An array of 2 integers used to represent one component of a simple or hierarchical **TopoGeometry**.

In the case of a simple TopoGeometry the first element of the array represents the identifier of a topological primitive and the second element represents its type (1:node, 2:edge, 3:face). In the case of a hierarchical TopoGeometry the first element of the array represents the identifier of a child TopoGeometry and the second element represents its layer identifier.

#### Note

For any given hierarchical TopoGeometry all child TopoGeometry elements will come from the same child layer, as specified in the topology.layer record for the layer of the TopoGeometry being defined.

#### Examples

```
SELECT te[1] AS id, te[2] AS type FROM
(SELECT ARRAY[1,2]::topology.topoelement AS te) f;
 id | type
----+-----
 1 | 2
```

```
SELECT ARRAY[1,2]::topology.topoelement;
 te

 {1,2}
```

```
--Example of what happens when you try to case a 3 element array to topoelement
-- NOTE: topoement has to be a 2 element array so fails dimension check
SELECT ARRAY[1,2,3]::topology.topoelement;
ERROR: value for domain topology.topoelement violates check constraint "dimensions"
```

#### See Also

[GetTopoGeomElements](#), [TopoElementArray](#), [TopoGeometry](#), [TopoGeom\\_addElement](#), [TopoGeom\\_remElement](#)

### 11.2.2 TopoElementArray

TopoElementArray — An array of TopoElement objects

#### Description

An array of 1 or more TopoElement objects, generally used to pass around components of TopoGeometry objects.

## Examples

```
SELECT '{{1,2},{4,3}}'::topology.topoelementarray As tea;
 tea

{{1,2},{4,3}}

-- more verbose equivalent --
SELECT ARRAY[ARRAY[1,2], ARRAY[4,3]]::topology.topoelementarray As tea;

 tea

{{1,2},{4,3}}

--using the array agg function packaged with topology --
SELECT topology.TopoElementArray_Agg(ARRAY[e,t]) As tea
 FROM generate_series(1,4) As e CROSS JOIN generate_series(1,3) As t;
 tea

{{1,1},{1,2},{1,3},{2,1},{2,2},{2,3},{3,1},{3,2},{3,3},{4,1},{4,2},{4,3}}
```

```
SELECT '{{1,2,4},{3,4,5}}'::topology.topoelementarray As tea;
ERROR: value for domain topology.topoelementarray violates check constraint "dimensions"
```

## See Also

[TopoElement](#), [GetTopoGeomElementArray](#), [TopoElementArray\\_Agg](#)

## 11.3 Topology and TopoGeometry Management

### 11.3.1 AddTopoGeometryColumn

**AddTopoGeometryColumn** — Adds a topogeometry column to an existing table, registers this new column as a layer in topology.layer and returns the new layer\_id.

#### Synopsis

```
integer AddTopoGeometryColumn(varchar topology_name, varchar schema_name, varchar table_name, varchar column_name,
varchar feature_type);
integer AddTopoGeometryColumn(varchar topology_name, varchar schema_name, varchar table_name, varchar column_name,
varchar feature_type, integer child_layer);
```

#### Description

Each TopoGeometry object belongs to a specific Layer of a specific Topology. Before creating a TopoGeometry object you need to create its TopologyLayer. A Topology Layer is an association of a feature-table with the topology. It also contain type and hierarchy information. We create a layer using the AddTopoGeometryColumn() function:

This function will both add the requested column to the table and add a record to the topology.layer table with all the given info.

If you don't specify [child\_layer] (or set it to NULL) this layer would contain Basic TopoGeometries (composed by primitive topology elements). Otherwise this layer will contain hierarchical TopoGeometries (composed by TopoGeometries from the child\_layer).

Once the layer is created (its id is returned by the AddTopoGeometryColumn function) you're ready to construct TopoGeometry objects in it

Valid `feature_types` are: POINT, LINE, POLYGON, COLLECTION

Availability: 1.?

### Examples

```
-- Note for this example we created our new table in the ma_topo schema
-- though we could have created it in a different schema -- in which case topology_name and ←
 schema_name would be different
CREATE SCHEMA ma;
CREATE TABLE ma.parcels(gid serial, parcel_id varchar(20) PRIMARY KEY, address text);
SELECT topology.AddTopoGeometryColumn('ma_topo', 'ma', 'parcels', 'topo', 'POLYGON');
```

```
CREATE SCHEMA ri;
CREATE TABLE ri.roads(gid serial PRIMARY KEY, road_name text);
SELECT topology.AddTopoGeometryColumn('ri_topo', 'ri', 'roads', 'topo', 'LINE');
```

### See Also

[CreateTopology](#), [CreateTopoGeom](#)

## 11.3.2 DropTopology

**DropTopology** — Use with caution: Drops a topology schema and deletes its reference from `topology.topology` table and references to tables in that schema from the `geometry_columns` table.

### Synopsis

integer **DropTopology**(varchar topology\_schema\_name);

### Description

Drops a topology schema and deletes its reference from `topology.topology` table and references to tables in that schema from the `geometry_columns` table. This function should be **USED WITH CAUTION**, as it could destroy data you care about. If the schema does not exist, it just removes reference entries the named schema.

Availability: 1.?

### Examples

Cascade drops the `ma_topo` schema and removes all references to it in `topology.topology` and `geometry_columns`.

```
SELECT topology.DropTopology('ma_topo');
```

### See Also

## 11.3.3 DropTopoGeometryColumn

**DropTopoGeometryColumn** — Drops the topogeometry column from the table named `table_name` in schema `schema_name` and unregisters the columns from `topology.layer` table.

**Synopsis**

text **DropTopoGeometryColumn**(varchar schema\_name, varchar table\_name, varchar column\_name);

**Description**

Drops the topogeometry column from the table named `table_name` in schema `schema_name` and unregisters the columns from `topology.layer` table. Returns summary of drop status. NOTE: it first sets all values to NULL before dropping to bypass referential integrity checks.

Availability: 1.?

**Examples**

```
SELECT topology.DropTopoGeometryColumn('ma_topo', 'parcel_topo', 'topo');
```

**See Also**

[AddTopoGeometryColumn](#)

**11.3.4 Populate\_Topology\_Layer**

`Populate_Topology_Layer` — Adds missing entries to `topology.layer` table by reading metadata from topo tables.

**Synopsis**

setof record **Populate\_Topology\_Layer**();

**Description**

Adds missing entries to the `topology.layer` table by inspecting topology constraints on tables. This function is useful for fixing up entries in topology catalog after restores of schemas with topo data.

It returns the list of entries created. Returned columns are `schema_name`, `table_name`, `feature_column`.

Availability: 2.3.0

**Examples**

```
SELECT CreateTopology('strk_topo');
CREATE SCHEMA strk;
CREATE TABLE strk.parcels(gid serial, parcel_id varchar(20) PRIMARY KEY, address text);
SELECT topology.AddTopoGeometryColumn('strk_topo', 'strk', 'parcels', 'topo', 'POLYGON');
-- this will return no records because this feature is already registered
SELECT *
 FROM topology.Populate_Topology_Layer();

-- let's rebuild
TRUNCATE TABLE topology.layer;

SELECT *
 FROM topology.Populate_Topology_Layer();

SELECT topology_id,layer_id, schema_name As sn, table_name As tn, feature_column As fc
FROM topology.layer;
```

```

schema_name | table_name | feature_column
-----+-----+-----
strk | parcels | topo
(1 row)

topology_id | layer_id | sn | tn | fc
-----+-----+-----+-----+-----
 2 | 2 | strk | parcels | topo
(1 row)

```

**See Also**[AddTopoGeometryColumn](#)**11.3.5 TopologySummary**

**TopologySummary** — Takes a topology name and provides summary totals of types of objects in topology

**Synopsis**

```
text TopologySummary(varchar topology_schema_name);
```

**Description**

Takes a topology name and provides summary totals of types of objects in topology.

Availability: 2.0.0

**Examples**

```

SELECT topology.topologysummary('city_data');
 topologysummary
-----+-----
Topology city_data (329), SRID 4326, precision: 0
22 nodes, 24 edges, 10 faces, 29 topogeoms in 5 layers
Layer 1, type Polygonal (3), 9 topogeoms
 Deploy: features.land_parcels.feature
Layer 2, type Puntal (1), 8 topogeoms
 Deploy: features.traffic_signs.feature
Layer 3, type Lineal (2), 8 topogeoms
 Deploy: features.city_streets.feature
Layer 4, type Polygonal (3), 3 topogeoms
Hierarchy level 1, child layer 1
 Deploy: features.big_parcels.feature
Layer 5, type Puntal (1), 1 topogeoms
Hierarchy level 1, child layer 2
 Deploy: features.big_signs.feature

```

**See Also**[Topology\\_Load\\_Tiger](#)

### 11.3.6 ValidateTopology

ValidateTopology — Returns a set of validate\_topology\_returntype objects detailing issues with topology

#### Synopsis

setof validate\_topology\_returntype **ValidateTopology**(varchar topology\_schema\_name);

#### Description

Returns a set of [validate\\_topology\\_returntype](#) objects detailing issues with topology. List of possible errors and what the returned ids represent are displayed below:

Error	id1	id2
edge crosses node	edge_id	node_id
invalid edge	edge_id	null
edge not simple	edge_id	null
edge crosses edge	edge_id	edge_id
edge start node geometry mis-match	edge_id	node_id
edge end node geometry mis-match	edge_id	node_id
face without edges	face_id	null
face has no rings	face_id	null
face overlaps face	face_id	face_id
face within face	inner face_id	outer face_id

Availability: 1.0.0

Enhanced: 2.0.0 more efficient edge crossing detection and fixes for false positives that were existent in prior versions.

Changed: 2.2.0 values for id1 and id2 were swapped for 'edge crosses node' to be consistent with error description.

#### Examples

```
SELECT * FROM topology.ValidateTopology('ma_topo');
 error | id1 | id2
-----+-----+-----
face without edges | 0 |
```

#### See Also

## 11.4 Topology Constructors

### 11.4.1 CreateTopology

CreateTopology — Creates a new topology schema and registers this new schema in the topology.topology table.

## Synopsis

```
integer CreateTopology(varchar topology_schema_name);
integer CreateTopology(varchar topology_schema_name, integer srid);
integer CreateTopology(varchar topology_schema_name, integer srid, double precision prec);
integer CreateTopology(varchar topology_schema_name, integer srid, double precision prec, boolean hasz);
```

## Description

Creates a new schema with name `topology_name` consisting of tables (`edge_data`, `face`, `node`, `relation` and registers this new topology in the `topology.topology` table. It returns the id of the topology in the `topology` table. The `srid` is the spatial reference identified as defined in `spatial_ref_sys` table for that topology. Topologies must be uniquely named. The tolerance is measured in the units of the spatial reference system. If the tolerance (`prec`) is not specified defaults to 0.

This is similar to the SQL/MM [ST\\_InitTopoGeo](#) but a bit more functional. `hasz` defaults to false if not specified.

Availability: 1.?

## Examples

This example creates a new schema called `ma_topo` that will store edges, faces, and relations in Massachusetts State Plane meters. The tolerance represents 1/2 meter since the spatial reference system is a meter based spatial reference system

```
SELECT topology.CreateTopology('ma_topo', 26986, 0.5);
```

Create Rhode Island topology in State Plane ft

```
SELECT topology.CreateTopology('ri_topo', 3438) As topoid;
topoid

2
```

## See Also

Section [4.3.1](#), [ST\\_InitTopoGeo](#), [Topology\\_Load\\_Tiger](#)

## 11.4.2 CopyTopology

**CopyTopology** — Makes a copy of a topology structure (nodes, edges, faces, layers and TopoGeometries).

### Synopsis

```
integer CopyTopology(varchar existing_topology_name, varchar new_name);
```

### Description

Creates a new topology with name `new_topology_name` and SRID and precision taken from `existing_topology_name`, copies all nodes, edges and faces in there, copies layers and their TopoGeometries too.

**Note**

The new rows in `topology.layer` will contain synthesized values for `schema_name`, `table_name` and `feature_column`. This is because the TopoGeometry will only exist as a definition but won't be available in any user-level table yet.

Availability: 2.0.0

## Examples

This example makes a backup of a topology called ma\_topo

```
SELECT topology.CopyTopology('ma_topo', 'ma_topo_bakup');
```

## See Also

Section [4.3.1](#), [CreateTopology](#)

### 11.4.3 ST\_InitTopoGeo

**ST\_InitTopoGeo** — Creates a new topology schema and registers this new schema in the topology.topology table and details summary of process.

## Synopsis

```
text ST_InitTopoGeo(varchar topology_schema_name);
```

## Description

This is an SQL-MM equivalent of [CreateTopology](#) but lacks the spatial reference and tolerance options of [CreateTopology](#) and outputs a text description of creation instead of topology id.

Availability: 1.?

This method implements the SQL/MM specification. SQL-MM 3 Topo-Geo and Topo-Net 3: Routine Details: X.3.17

## Examples

```
SELECT topology.ST_InitTopoGeo('topo_schema_to_create') AS topocreation;
 atopocreation

Topology-Geometry 'topo_schema_to_create' (id:7) created.
```

## See Also

[CreateTopology](#)

### 11.4.4 ST\_CreateTopoGeo

**ST\_CreateTopoGeo** — Adds a collection of geometries to a given empty topology and returns a message detailing success.

## Synopsis

```
text ST_CreateTopoGeo(varchar atopology, geometry acollection);
```

**Description**

Adds a collection of geometries to a given empty topology and returns a message detailing success.

Useful for populating an empty topology.

Availability: 2.0

This method implements the SQL/MM specification. SQL-MM: Topo-Geo and Topo-Net 3: Routine Details -- X.3.18

**Examples**

```
-- Populate topology --
SELECT topology.ST_CreateTopoGeo('ri_topo',
 ST_GeomFromText('MULTILINESTRING((384744 236928,384750 236923,384769 236911,384799 ←

[AddTopoGeometryColumn](#), [CreateTopology](#), [DropTopology](#)

**11.4.5 TopoGeo\_AddPoint**

TopoGeo\_AddPoint — Adds a point to an existing topology using a tolerance and possibly splitting an existing edge.

**Synopsis**

integer **TopoGeo\_AddPoint**(varchar toponame, geometry apoint, float8 tolerance);

**Description**

Adds a point to an existing topology and return its identifier. The given point will snap to existing nodes or edges within given tolerance. An existing edge may be split by the snapped point.

Availability: 2.0.0

**See Also**

[TopoGeo\\_AddLineString](#), [TopoGeo\\_AddPolygon](#), [AddNode](#), [CreateTopology](#)

### 11.4.6 TopoGeo\_AddLineString

`TopoGeo_AddLineString` — Adds a linestring to an existing topology using a tolerance and possibly splitting existing edges/faces. Returns edge identifiers

**Synopsis**

SETOF integer **TopoGeo\_AddLineString**(varchar toponame, geometry aline, float8 tolerance);

**Description**

Adds a linestring to an existing topology and return a set of edge identifiers forming it up. The given line will snap to existing nodes or edges within given tolerance. Existing edges and faces may be split by the line.

Availability: 2.0.0

**See Also**

[TopoGeo\\_AddPoint](#), [TopoGeo\\_AddPolygon](#), [AddEdge](#), [CreateTopology](#)

### 11.4.7 TopoGeo\_AddPolygon

`TopoGeo_AddPolygon` — Adds a polygon to an existing topology using a tolerance and possibly splitting existing edges/faces.

**Synopsis**

integer **TopoGeo\_AddPolygon**(varchar atopology, geometry apoly, float8 atolerance);

**Description**

Adds a polygon to an existing topology and return a set of face identifiers forming it up. The boundary of the given polygon will snap to existing nodes or edges within given tolerance. Existing edges and faces may be split by the boundary of the new polygon.

Availability: 2.0.0

**See Also**

[TopoGeo\\_AddPoint](#), [TopoGeo\\_AddLineString](#), [AddFace](#), [CreateTopology](#)

## 11.5 Topology Editors

### 11.5.1 ST\_AddIsoNode

`ST_AddIsoNode` — Adds an isolated node to a face in a topology and returns the nodeid of the new node. If face is null, the node is still created.

---

## Synopsis

integer **ST\_AddIsoNode**(varchar atopology, integer aface, geometry apoint);

## Description

Adds an isolated node with point location `apoint` to an existing face with faceid `aface` to a topology `atopology` and returns the nodeid of the new node.

If the spatial reference system (srid) of the point geometry is not the same as the topology, the `apoint` is not a point geometry, the point is null, or the point intersects an existing edge (even at the boundaries) then an exception is thrown. If the point already exists as a node, an exception is thrown.

If `aface` is not null and the `apoint` is not within the face, then an exception is thrown.

Availability: 1.?

This method implements the SQL/MM specification. SQL-MM: Topo-Net Routines: X+1.3.1

## Examples

### See Also

[AddNode](#), [CreateTopology](#), [DropTopology](#), [ST\\_Intersects](#)

## 11.5.2 ST\_AddIsoEdge

**ST\_AddIsoEdge** — Adds an isolated edge defined by geometry `alinestring` to a topology connecting two existing isolated nodes `anode` and `anothernode` and returns the edge id of the new edge.

## Synopsis

integer **ST\_AddIsoEdge**(varchar atopology, integer anode, integer anothernode, geometry alinestring);

## Description

Adds an isolated edge defined by geometry `alinestring` to a topology connecting two existing isolated nodes `anode` and `anothernode` and returns the edge id of the new edge.

If the spatial reference system (srid) of the `alinestring` geometry is not the same as the topology, any of the input arguments are null, or the nodes are contained in more than one face, or the nodes are start or end nodes of an existing edge, then an exception is thrown.

If the `alinestring` is not within the face of the face the `anode` and `anothernode` belong to, then an exception is thrown.

If the `anode` and `anothernode` are not the start and end points of the `alinestring` then an exception is thrown.

Availability: 1.?

This method implements the SQL/MM specification. SQL-MM: Topo-Geo and Topo-Net 3: Routine Details: X.3.4

## Examples

### See Also

[ST\\_AddIsoNode](#), [ST\\_IsSimple](#), [ST\\_Within](#)

---

### 11.5.3 ST\_AddEdgeNewFaces

`ST_AddEdgeNewFaces` — Add a new edge and, if in doing so it splits a face, delete the original face and replace it with two new faces.

#### Synopsis

```
integer ST_AddEdgeNewFaces(varchar atopology, integer anode, integer anothernode, geometry acurve);
```

#### Description

Add a new edge and, if in doing so it splits a face, delete the original face and replace it with two new faces. Returns the id of the newly added edge.

Updates all existing joined edges and relationships accordingly.

If any arguments are null, the given nodes are unknown (must already exist in the `node` table of the topology schema) , the `acurve` is not a `LINestring`, the `anode` and `anothernode` are not the start and endpoints of `acurve` then an error is thrown.

If the spatial reference system (`srid`) of the `acurve` geometry is not the same as the topology an exception is thrown.

Availability: 2.0

This method implements the SQL/MM specification. SQL-MM: Topo-Geo and Topo-Net 3: Routine Details: X.3.12

#### Examples

#### See Also

[ST\\_RemEdgeNewFace](#)

[ST\\_AddEdgeModFace](#)

### 11.5.4 ST\_AddEdgeModFace

`ST_AddEdgeModFace` — Add a new edge and, if in doing so it splits a face, modify the original face and add a new face.

#### Synopsis

```
integer ST_AddEdgeModFace(varchar atopology, integer anode, integer anothernode, geometry acurve);
```

#### Description

Add a new edge and, if doing so splits a face, modify the original face and add a new one.

#### Note

If possible, the new face will be created on left side of the new edge. This will not be possible if the face on the left side will need to be the Universe face (unbounded).

Returns the id of the newly added edge.

Updates all existing joined edges and relationships accordingly.

If any arguments are null, the given nodes are unknown (must already exist in the `node` table of the topology schema) , the `acurve` is not a `LINestring`, the `anode` and `anothernode` are not the start and endpoints of `acurve` then an error is thrown.

If the spatial reference system (srid) of the `acurve` geometry is not the same as the topology an exception is thrown.

Availability: 2.0

This method implements the SQL/MM specification. SQL-MM: Topo-Geo and Topo-Net 3: Routine Details: X.3.13

### Examples

### See Also

[ST\\_RemEdgeModFace](#)

[ST\\_AddEdgeNewFaces](#)

## 11.5.5 ST\_RemEdgeNewFace

`ST_RemEdgeNewFace` — Removes an edge and, if the removed edge separated two faces, delete the original faces and replace them with a new face.

### Synopsis

```
integer ST_RemEdgeNewFace(varchar atopology, integer anedge);
```

### Description

Removes an edge and, if the removed edge separated two faces, delete the original faces and replace them with a new face.

Returns the id of a newly created face or `NULL`, if no new face is created. No new face is created when the removed edge is dangling or isolated or confined with the universe face (possibly making the universe flood into the face on the other side).

Updates all existing joined edges and relationships accordingly.

Refuses to remove an edge participating in the definition of an existing TopoGeometry. Refuses to heal two faces if any TopoGeometry is defined by only one of them (and not the other).

If any arguments are null, the given edge is unknown (must already exist in the `edge` table of the topology schema), the topology name is invalid then an error is thrown.

Availability: 2.0

This method implements the SQL/MM specification. SQL-MM: Topo-Geo and Topo-Net 3: Routine Details: X.3.14

### Examples

### See Also

[ST\\_RemEdgeModFace](#)

[ST\\_AddEdgeNewFaces](#)

---

### 11.5.6 ST\_RemEdgeModFace

`ST_RemEdgeModFace` — Removes an edge and, if the removed edge separated two faces, delete one of the them and modify the other to take the space of both.

#### Synopsis

```
integer ST_RemEdgeModFace(varchar atopology, integer anedge);
```

#### Description

Removes an edge and, if the removed edge separated two faces, delete one of the them and modify the other to take the space of both. Preferentially keeps the face on the right, to be symmetric with `ST_AddEdgeModFace` also keeping it. Returns the id of the face remaining in place of the removed edge.

Updates all existing joined edges and relationships accordingly.

Refuses to remove an edge participating in the definition of an existing TopoGeometry. Refuses to heal two faces if any TopoGeometry is defined by only one of them (and not the other).

If any arguments are null, the given edge is unknown (must already exist in the `edge` table of the topology schema), the topology name is invalid then an error is thrown.

Availability: 2.0

This method implements the SQL/MM specification. SQL-MM: Topo-Geo and Topo-Net 3: Routine Details: X.3.15

#### Examples

#### See Also

[ST\\_AddEdgeModFace](#)

[ST\\_RemEdgeNewFace](#)

### 11.5.7 ST\_ChangeEdgeGeom

`ST_ChangeEdgeGeom` — Changes the shape of an edge without affecting the topology structure.

#### Synopsis

```
integer ST_ChangeEdgeGeom(varchar atopology, integer anedge, geometry acurve);
```

#### Description

Changes the shape of an edge without affecting the topology structure.

If any arguments are null, the given edge does not exist in the `edge` table of the topology schema, the `acurve` is not a `LINestring`, the `anode` and `anothernode` are not the start and endpoints of `acurve` or the modification would change the underlying topology then an error is thrown.

If the spatial reference system (`srid`) of the `acurve` geometry is not the same as the topology an exception is thrown.

If the new `acurve` is not simple, then an error is thrown.

If moving the edge from old to new position would hit an obstacle then an error is thrown.

---

Availability: 1.1.0

Enhanced: 2.0.0 adds topological consistency enforcement

This method implements the SQL/MM specification. SQL-MM: Topo-Geo and Topo-Net 3: Routine Details X.3.6

### Examples

```
SELECT topology.ST_ChangeEdgeGeom('ma_topo', 1,
 ST_GeomFromText('LINESTRING(227591.9 893900.4,227622.6 893844.3,227641.6 893816.6, ←
 227704.5 893778.5)', 26986));

**11.5.11 ST\_MoveIsoNode**

`ST_MoveIsoNode` — Moves an isolated node in a topology from one point to another. If new `apoint` geometry exists as a node an error is thrown. Returns description of move.

**Synopsis**

```
text ST_MoveIsoNode(varchar atopology, integer anedge, geometry apoint);
```

**Description**

Moves an isolated node in a topology from one point to another. If new `apoint` geometry exists as a node an error is thrown.

If any arguments are null, the `apoint` is not a point, the existing node is not isolated (is a start or end point of an existing edge), new node location intersects an existing edge (even at the end points) then an exception is thrown.

If the spatial reference system (srid) of the point geometry is not the same as the topology an exception is thrown.

Availability: 1.?

This method implements the SQL/MM specification. SQL-MM: Topo-Net Routines: X.3.2

**Examples**

```
-- Add an isolated node with no face --

**11.5.12 ST\_NewEdgesSplit**

`ST_NewEdgesSplit` — Split an edge by creating a new node along an existing edge, deleting the original edge and replacing it with two new edges. Returns the id of the new node created that joins the new edges.

**Synopsis**

```
integer ST_NewEdgesSplit(varchar atopology, integer anedge, geometry apoint);
```

## Description

Split an edge with edge id `anedge` by creating a new node with point location `apoint` along current edge, deleting the original edge and replacing it with two new edges. Returns the id of the new node created that joins the new edges. Updates all existing joined edges and relationships accordingly.

If the spatial reference system (srid) of the point geometry is not the same as the topology, the `apoint` is not a point geometry, the point is null, the point already exists as a node, the edge does not correspond to an existing edge or the point is not within the edge then an exception is thrown.

Availability: 1.?

This method implements the SQL/MM specification. SQL-MM: Topo-Net Routines: X.3.8

## Examples

```
-- Add an edge --
SELECT topology.AddEdge('ma_topo', ST_GeomFromText('LINESTRING(227575 893917,227592 893900) ←
', 26986)) As edgeid;
-- result-
edgeid

 2
-- Split the new edge --

### 11.5.13 ST\_RemoveIsoNode

`ST_RemoveIsoNode` — Removes an isolated node and returns description of action. If the node is not isolated (is start or end of an edge), then an exception is thrown.

#### Synopsis

```
text ST_RemoveIsoNode(varchar atopology, integer anode);
```

#### Description

Removes an isolated node and returns description of action. If the node is not isolated (is start or end of an edge), then an exception is thrown.

Availability: 1.?

This method implements the SQL/MM specification. SQL-MM: Topo-Geo and Topo-Net 3: Routine Details: X+1.3.3

**Examples**

```
-- Remove an isolated node with no face --
SELECT topology.ST_RemoveIsoNode('ma_topo', 7) As result;
 result

Isolated node 7 removed
```

**See Also**

[ST\\_AddIsoNode](#)

**11.5.14 ST\_RemoveIsoEdge**

**ST\_RemoveIsoEdge** — Removes an isolated edge and returns description of action. If the edge is not isolated, then an exception is thrown.

**Synopsis**

text **ST\_RemoveIsoEdge**(varchar atopology, integer anedge);

**Description**

Removes an isolated edge and returns description of action. If the edge is not isolated, then an exception is thrown.

Availability: 1.?

This method implements the SQL/MM specification. SQL-MM: Topo-Geo and Topo-Net 3: Routine Details: X+1.3.3

**Examples**

```
-- Remove an isolated node with no face --
SELECT topology.ST_RemoveIsoNode('ma_topo', 7) As result;
 result

Isolated node 7 removed
```

**11.6 Topology Accessors****11.6.1 GetEdgeByPoint**

**GetEdgeByPoint** — Find the edge-id of an edge that intersects a given point

**Synopsis**

integer **GetEdgeByPoint**(varchar atopology, geometry apoint, float8 tol);

## Retrieve the id of an edge that intersects a Point

The function returns an integer (id-edge) given a topology, a POINT and a tolerance. If tolerance = 0 then the point has to intersect the edge.

If the point doesn't intersect an edge, returns 0 (zero).

If use tolerance > 0 and there is more than one edge near the point then an exception is thrown.

### Note

If tolerance = 0, the function use ST\_Intersects otherwise uses ST\_DWithin.

Availability: 2.0.0 - requires GEOS >= 3.3.0.

## Examples

These examples use edges we created in [AddEdge](#)

```
SELECT topology.GetEdgeByPoint('ma_topo',geom, 1) As withlmtol, topology.GetEdgeByPoint(' ←
 ma_topo',geom,0) As withnotol
FROM ST_GeomFromEWKT('SRID=26986;POINT(227622.6 893843)') As geom;
withlmtol | withnotol
-----+-----
 2 | 0
```

```
SELECT topology.GetEdgeByPoint('ma_topo',geom, 1) As nearnode
FROM ST_GeomFromEWKT('SRID=26986;POINT(227591.9 893900.4)') As geom;

-- get error --
ERROR: Two or more edges found
```

### 11.6.2 GetFaceByPoint

GetFaceByPoint — Find the face-id of a face that intersects a given point

#### Synopsis

```
integer GetFaceByPoint(varchar atopology, geometry apoint, float8 tol);
```

#### Description

Retrieve the id of a face that intersects a Point.

The function returns an integer (id-face) given a topology, a POINT and a tolerance. If tolerance = 0 then the point has to intersect the face.

If the point doesn't intersect a face, returns 0 (zero).

If use tolerance > 0 and there is more than one face near the point then an exception is thrown.

**Note**

If tolerance = 0, the function uses ST\_Intersects otherwise uses ST\_DWithin.

Availability: 2.0.0 - requires GEOS >= 3.3.0.

**Examples**

These examples use edges faces created in [AddFace](#)

```
SELECT topology.GetFaceByPoint('ma_topo',geom, 10) As withlmtol, topology.GetFaceByPoint(' ←
ma_topo',geom,0) As withnotol
FROM ST_GeomFromEWKT('POINT(234604.6 899382.0)') As geom;
```

```
withlmtol | withnotol
-----+-----
1 | 0
```

```
SELECT topology.GetFaceByPoint('ma_topo',geom, 1) As nearnode
FROM ST_GeomFromEWKT('POINT(227591.9 893900.4)') As geom;
```

```
-- get error --
ERROR: Two or more faces found
```

**See Also**

**11.6.3 GetNodeByPoint**

GetNodeByPoint — Find the id of a node at a point location

**Synopsis**

integer **GetNodeByPoint**(varchar atopology, geometry point, float8 tol);

**Retrieve the id of a node at a point location**

The function return an integer (id-node) given a topology, a POINT and a tolerance. If tolerance = 0 mean exactly intersection otherwise retrieve the node from an interval.

If there isn't a node at the point, it return 0 (zero).

If use tolerance > 0 and near the point there are more than one node it throw an exception.

**Note**

If tolerance = 0, the function use ST\_Intersects otherwise will use ST\_DWithin.

Availability: 2.0.0 - requires GEOS >= 3.3.0.

## Examples

These examples use edges we created in [AddEdge](#)

```
SELECT topology.GetNodeByPoint('ma_topo',geom, 1) As nearnode
FROM ST_GeomFromEWKT('SRID=26986;POINT(227591.9 893900.4)') As geom;
nearnode

 2
```

```
SELECT topology.GetNodeByPoint('ma_topo',geom, 1000) As too_much_tolerance
FROM ST_GeomFromEWKT('SRID=26986;POINT(227591.9 893900.4)') As geom;

----get error--
ERROR: Two or more nodes found
```

### 11.6.4 GetTopologyID

**GetTopologyID** — Returns the id of a topology in the topology.topology table given the name of the topology.

#### Synopsis

integer **GetTopologyID**(varchar toponame);

#### Description

Returns the id of a topology in the topology.topology table given the name of the topology.

Availability: 1.?

#### Examples

```
SELECT topology.GetTopologyID('ma_topo') As topo_id;
topo_id

 1
```

## See Also

[CreateTopology](#), [DropTopology](#), [GetTopologyName](#), [GetTopologySRID](#)

### 11.6.5 GetTopologySRID

**GetTopologySRID** — Returns the SRID of a topology in the topology.topology table given the name of the topology.

#### Synopsis

integer **GetTopologyID**(varchar toponame);

## Description

Returns the spatial reference id of a topology in the topology.topology table given the name of the topology.

Availability: 2.0.0

## Examples

```
SELECT topology.GetTopologySRID('ma_topo') As SRID;
SRID

4326
```

## See Also

[CreateTopology](#), [DropTopology](#), [GetTopologyName](#), [GetTopologyID](#)

### 11.6.6 GetTopologyName

GetTopologyName — Returns the name of a topology (schema) given the id of the topology.

## Synopsis

varchar **GetTopologyName**(integer topology\_id);

## Description

Returns the topology name (schema) of a topology from the topology.topology table given the topology id of the topology.

Availability: 1.?

## Examples

```
SELECT topology.GetTopologyName(1) As topo_name;
topo_name

ma_topo
```

## See Also

[CreateTopology](#), [DropTopology](#), [GetTopologyID](#), [GetTopologySRID](#)

### 11.6.7 ST\_GetFaceEdges

ST\_GetFaceEdges — Returns a set of ordered edges that bound a face.

## Synopsis

getfaceedges\_returntype **ST\_GetFaceEdges**(varchar atopology, integer aface);

---

**Description**

Returns a set of ordered edges that bound a face. Each output consists of a sequence and edgeid. Sequence numbers start with value 1.

Enumeration of each ring edges start from the edge with smallest identifier. Order of edges follows a left-hand-rule (bound face is on the left of each directed edge).

Availability: 2.0

This method implements the SQL/MM specification. SQL-MM 3 Topo-Geo and Topo-Net 3: Routine Details: X.3.5

**Examples**

```
-- Returns the edges bounding face 1
SELECT (topology.ST_GetFaceEdges('tt', 1)).*;
-- result --
sequence | edge
-----+-----
 1 | -4
 2 | 5
 3 | 7
 4 | -6
 5 | 1
 6 | 2
 7 | 3
(7 rows)
```

```
-- Returns the sequence, edge id
-- and geometry of the edges that bound face 1
-- If you just need geom and seq, can use ST_GetFaceGeometry
SELECT t.seq, t.edge, geom
FROM topology.ST_GetFaceEdges('tt',1) As t(seq,edge)
INNER JOIN tt.edge AS e ON abs(t.edge) = e.edge_id;
```

**See Also**

[GetRingEdges](#), [AddFace](#), [ST\\_GetFaceGeometry](#)

**11.6.8 ST\_GetFaceGeometry**

`ST_GetFaceGeometry` — Returns the polygon in the given topology with the specified face id.

**Synopsis**

geometry `ST_GetFaceGeometry`(varchar atopology, integer aface);

**Description**

Returns the polygon in the given topology with the specified face id. Builds the polygon from the edges making up the face.

Availability: 1.?

This method implements the SQL/MM specification. SQL-MM 3 Topo-Geo and Topo-Net 3: Routine Details: X.3.16

## Examples

```
-- Returns the wkt of the polygon added with AddFace
SELECT ST_AsText(topology.ST_GetFaceGeometry('ma_topo', 1)) As facegeomwkt;
-- result --
 facegeomwkt

POLYGON((234776.9 899563.7,234896.5 899456.7,234914 899436.4,234946.6 899356.9,
234872.5 899328.7,234891 899285.4,234992.5 899145,234890.6 899069,
234755.2 899255.4,234612.7 899379.4,234776.9 899563.7))
```

## See Also

[AddFace](#)

### 11.6.9 GetRingEdges

`GetRingEdges` — Returns the ordered set of signed edge identifiers met by walking on an a given edge side.

#### Synopsis

```
getfaceedges_returntype GetRingEdges(varchar atopology, integer aring, integer max_edges=null);
```

#### Description

Returns the ordered set of signed edge identifiers met by walking on an a given edge side. Each output consists of a sequence and a signed edge id. Sequence numbers start with value 1.

If you pass a positive edge id, the walk starts on the left side of the corresponding edge and follows the edge direction. If you pass a negative edge id, the walk starts on the right side of it and goes backward.

If `max_edges` is not null no more than those records are returned by that function. This is meant to be a safety parameter when dealing with possibly invalid topologies.

#### Note

This function uses edge ring linking metadata.

Availability: 2.0.0

## See Also

[ST\\_GetFaceEdges](#), [GetNodeEdges](#)

### 11.6.10 GetNodeEdges

`GetNodeEdges` — Returns an ordered set of edges incident to the given node.

#### Synopsis

```
getfaceedges_returntype GetNodeEdges(varchar atopology, integer anode);
```

## Description

Returns an ordered set of edges incident to the given node. Each output consists of a sequence and a signed edge id. Sequence numbers start with value 1. A positive edge starts at the given node. A negative edge ends into the given node. Closed edges will appear twice (with both signs). Order is clockwise starting from northbound.

### Note

This function computes ordering rather than deriving from metadata and is thus usable to build edge ring linking.

---

Availability: 2.0

## See Also

[GetRingEdges](#), [ST\\_Azimuth](#)

## 11.7 Topology Processing

### 11.7.1 Polygonize

Polygonize — Find and register all faces defined by topology edges

#### Synopsis

```
text Polygonize(varchar toponame);
```

#### Description

Register all faces that can be built out a topology edge primitives.

The target topology is assumed to contain no self-intersecting edges.

### Note

Already known faces are recognized, so it is safe to call Polygonize multiple times on the same topology.

---

### Note

This function does not use nor set the `next_left_edge` and `next_right_edge` fields of the edge table.

---

Availability: 2.0.0

## See Also

[AddFace](#), [ST\\_Polygonize](#)

---

## 11.7.2 AddNode

**AddNode** — Adds a point node to the node table in the specified topology schema and returns the nodeid of new node. If point already exists as node, the existing nodeid is returned.

### Synopsis

```
integer AddNode(varchar toponame, geometry apoint, boolean allowEdgeSplitting=false, boolean computeContainingFace=false);
```

### Description

Adds a point node to the node table in the specified topology schema. The **AddEdge** function automatically adds start and end points of an edge when called so not necessary to explicitly add nodes of an edge.

If any edge crossing the node is found either an exception is raised or the edge is split, depending on the `allowEdgeSplitting` parameter value.

If `computeContainingFace` is true a newly added node would get the correct containing face computed.

#### Note

If the `apoint` geometry already exists as a node, the node is not added but the existing nodeid is returned.

Availability: 2.0.0

### Examples

```
SELECT topology.AddNode('ma_topo', ST_GeomFromText('POINT(227641.6 893816.5)', 26986)) As ←
 nodeid;
-- result --
nodeid

4
```

### See Also

[AddEdge](#), [CreateTopology](#)

## 11.7.3 AddEdge

**AddEdge** — Adds a linestring edge to the edge table and associated start and end points to the point nodes table of the specified topology schema using the specified linestring geometry and returns the edgeid of the new (or existing) edge.

### Synopsis

```
integer AddEdge(varchar toponame, geometry aline);
```

## Description

Adds an edge to the edge table and associated nodes to the nodes table of the specified `toponame` schema using the specified linestring geometry and returns the `edgeid` of the new or existing record. The newly added edge has "universe" face on both sides and links to itself.

### Note

If the `aline` geometry crosses, overlaps, contains or is contained by an existing linestring edge, then an error is thrown and the edge is not added.

### Note

The geometry of `aline` must have the same `srid` as defined for the topology otherwise an invalid spatial reference sys error will be thrown.

Availability: 2.0.0 requires GEOS >= 3.3.0.

## Examples

```
SELECT topology.AddEdge('ma_topo', ST_GeomFromText('LINESTRING(227575.8 893917.2,227591.9 893900.4)', 26986)) As edgeid;
-- result-
edgeid

1

SELECT topology.AddEdge('ma_topo', ST_GeomFromText('LINESTRING(227591.9 893900.4,227622.6 893844.2,227641.6 893816.5, 227704.5 893778.5)', 26986)) As edgeid;
-- result --
edgeid

2

SELECT topology.AddEdge('ma_topo', ST_GeomFromText('LINESTRING(227591.2 893900, 227591.9 893900.4, 227704.5 893778.5)', 26986)) As edgeid;
-- gives error --
ERROR: Edge intersects (not on endpoints) with existing edge 1
```

## See Also

## 11.7.4 AddFace

`AddFace` — Registers a face primitive to a topology and gets its identifier.

### Synopsis

integer **AddFace**(varchar toponame, geometry apolygon, boolean force\_new=false);

## Description

Registers a face primitive to a topology and gets its identifier.

For a newly added face, the edges forming its boundaries and the ones contained in the face will be updated to have correct values in the `left_face` and `right_face` fields. Isolated nodes contained in the face will also be updated to have a correct `containing_face` field value.

### Note

This function does not use nor set the `next_left_edge` and `next_right_edge` fields of the edge table.

The target topology is assumed to be valid (containing no self-intersecting edges). An exception is raised if: The polygon boundary is not fully defined by existing edges or the polygon overlaps an existing face.

If the `apolygon` geometry already exists as a face, then: if `force_new` is false (the default) the face id of the existing face is returned; if `force_new` is true a new id will be assigned to the newly registered face.

### Note

When a new registration of an existing face is performed (`force_new=true`), no action will be taken to resolve dangling references to the existing face in the edge, node or relation tables, nor will the MBR field of the existing face record be updated. It is up to the caller to deal with that.

### Note

The `apolygon` geometry must have the same `srid` as defined for the topology otherwise an invalid spatial reference sys error will be thrown.

Availability: 2.0.0

## Examples

```
-- first add the edges we use generate_series as an iterator (the below
-- will only work for polygons with < 10000 points because of our max in gs)

**11.7.5 ST\_Simplify**

**ST\_Simplify** — Returns a "simplified" geometry version of the given TopoGeometry using the Douglas-Peucker algorithm.

**Synopsis**

```
geometry ST_Simplify(TopoGeometry geomA, float tolerance);
```

**Description**

Returns a "simplified" geometry version of the given TopoGeometry using the Douglas-Peucker algorithm on each component edge.

**Note**

The returned geometry may be non-simple or non-valid.  
Splitting component edges may help retaining simplicity/validity.

Performed by the GEOS module.

Availability: 2.1.0

**See Also**

Geometry [ST\\_Simplify](#), [ST\\_IsSimple](#), [ST\\_IsValid](#), [ST\\_ModEdgeSplit](#)

**11.8 TopoGeometry Constructors****11.8.1 CreateTopoGeom**

**CreateTopoGeom** — Creates a new topo geometry object from topo element array - `tg_type`: 1:[multi]point, 2:[multi]line, 3:[multi]poly, 4:collection

## Synopsis

```
topogeometry CreateTopoGeom(vchar toponame, integer tg_type, integer layer_id, topoelementarray tg_objs);
topogeometry CreateTopoGeom(vchar toponame, integer tg_type, integer layer_id);
```

## Description

Creates a topogeometry object for layer denoted by `layer_id` and registers it in the relations table in the `toponame` schema.

`tg_type` is an integer: 1:[multi]point (punctal), 2:[multi]line (lineal), 3:[multi]poly (areal), 4:collection. `layer_id` is the layer id in the `topology.layer` table.

punctal layers are formed from set of nodes, lineal layers are formed from a set of edges, areal layers are formed from a set of faces, and collections can be formed from a mixture of nodes, edges, and faces.

Omitting the array of components generates an empty TopoGeometry object.

Availability: 1.?

## Examples: Form from existing edges

Create a topogeom in `ri_topo` schema for layer 2 (our `ri_roads`), of type (2) LINE, for the first edge (we loaded in `ST_CreateTopoGeo`).

```
INSERT INTO ri.ri_roads(road_name, topo) VALUES('Unknown', topology.CreateTopoGeom('ri_topo' ←
 ',2,2, '{{1,2}}'::topology.topoelementarray);
```

## Examples: Convert an areal geometry to best guess topogeometry

Lets say we have geometries that should be formed from a collection of faces. We have for example `blockgroups` table and want to know the topo geometry of each block group. If our data was perfectly aligned, we could do this:

```
-- create our topo geometry column --
SELECT topology.AddTopoGeometryColumn(
 'topo_boston',
 'boston', 'blockgroups', 'topo', 'POLYGON');

-- addtopogeometrycolumn --
1

-- update our column assuming
-- everything is perfectly aligned with our edges
UPDATE boston.blockgroups AS bg
 SET topo = topology.CreateTopoGeom('topo_boston'
 ,3,1
 , foo.bfaces)
FROM (SELECT b.gid, topology.TopoElementArray_Agg(ARRAY[f.face_id,3]) As bfaces
 FROM boston.blockgroups As b
 INNER JOIN topo_boston.face As f ON b.geom && f.mbr
 WHERE ST_Covers(b.geom, topology.ST_GetFaceGeometry('topo_boston', f.face_id))
 GROUP BY b.gid) As foo
WHERE foo.gid = bg.gid;
```

```
--the world is rarely perfect allow for some error
--count the face if 50% of it falls
-- within what we think is our blockgroup boundary
UPDATE boston.blockgroups AS bg
 SET topo = topology.CreateTopoGeom('topo_boston'
 ,3,1
```

```

 , foo.bfaces)
FROM (SELECT b.gid, topology.TopoElementArray_Agg(ARRAY[f.face_id,3]) As bfaces
 FROM boston.blockgroups As b
 INNER JOIN topo_boston.face As f ON b.geom && f.mbr
 WHERE ST_Covers(b.geom, topology.ST_GetFaceGeometry('topo_boston', f.face_id))
 OR
 (ST_Intersects(b.geom, topology.ST_GetFaceGeometry('topo_boston', f.face_id))
 AND ST_Area(ST_Intersection(b.geom, topology.ST_GetFaceGeometry('topo_boston', ←
 f.face_id))) >
 ST_Area(topology.ST_GetFaceGeometry('topo_boston', f.face_id))*0.5
)
 GROUP BY b.gid) As foo
WHERE foo.gid = bg.gid;

-- and if we wanted to convert our topogeometry back
-- to a denormalized geometry aligned with our faces and edges
-- cast the topo to a geometry
-- The really cool thing is my new geometries
-- are now aligned with my tiger street centerlines
UPDATE boston.blockgroups SET new_geom = topo::geometry;

```

**See Also**

[AddTopoGeometryColumn](#), [toTopoGeom](#) [ST\\_CreateTopoGeo](#), [ST\\_GetFaceGeometry](#), [TopoElementArray](#), [TopoElementArray\\_Agg](#)

**11.8.2 toTopoGeom**

toTopoGeom — Converts a simple Geometry into a topo geometry

**Synopsis**

```

topogeometry toTopoGeom(geometry geom, varchar toponame, integer layer_id, float8 tolerance);
topogeometry toTopoGeom(geometry geom, topogeometry topogeom, float8 tolerance);

```

**Description**

Converts a simple Geometry into a [TopoGeometry](#).

Topological primitives required to represent the input geometry will be added to the underlying topology, possibly splitting existing ones, and they will be associated with the output TopoGeometry in the `relation` table.

Existing TopoGeometry objects (with the possible exception of `topogeom`, if given) will retain their shapes.

When `tolerance` is given it will be used to snap the input geometry to existing primitives.

In the first form a new TopoGeometry will be created for the given layer (`layer_id`) of the given topology (`toponame`).

In the second form the primitives resulting from the conversion will be added to the pre-existing TopoGeometry (`topogeom`), possibly adding space to its final shape. To have the new shape completely replace the old one see [clearTopoGeom](#).

Availability: 2.0

Enhanced: 2.1.0 adds the version taking an existing TopoGeometry.

## Examples

This is a full self-contained workflow

```
-- do this if you don't have a topology setup already
-- creates topology not allowing any tolerance
SELECT topology.CreateTopology('topo_boston_test', 2249);
-- create a new table
CREATE TABLE nei_topo(gid serial primary key, nei varchar(30));
--add a topogeometry column to it
SELECT topology.AddTopoGeometryColumn('topo_boston_test', 'public', 'nei_topo', 'topo', ' ←
MULTIPOLYGON') As new_layer_id;
new_layer_id

1

--use new layer id in populating the new topogeometry column
-- we add the topogeoms to the new layer with 0 tolerance
INSERT INTO nei_topo(nei, topo)
SELECT nei, topology.toTopoGeom(geom, 'topo_boston_test', 1)
FROM neighborhoods
WHERE gid BETWEEN 1 and 15;

--use to verify what has happened --
SELECT * FROM
 topology.TopologySummary('topo_boston_test');

-- summary--
Topology topo_boston_test (5), SRID 2249, precision 0
61 nodes, 87 edges, 35 faces, 15 topogeoms in 1 layers
Layer 1, type Polygonal (3), 15 topogeoms
Deploy: public.nei_topo.topo

-- Shrink all TopoGeometry polygons by 10 meters
UPDATE nei_topo SET topo = ST_Buffer(clearTopoGeom(topo), -10);

-- Get the no-one-lands left by the above operation
-- I think GRASS calls this "polygon0 layer"
SELECT ST_GetFaceGeometry('topo_boston_test', f.face_id)
FROM topo_boston_test.face f
WHERE f.face_id > 0 -- don't consider the universe face
AND NOT EXISTS (-- check that no TopoGeometry references the face
 SELECT * FROM topo_boston_test.relation
 WHERE layer_id = 1 AND element_id = f.face_id
);
```

### 11.8.3 TopoElementArray\_Agg

TopoElementArray\_Agg — Returns a topoelementarray for a set of element\_id, type arrays (topoelements)

#### Synopsis

```
topoelementarray TopoElementArray_Agg(topoelement set tefield);
```

## Description

Used to create a [TopoElementArray](#) from a set of [TopoElement](#).

Availability: 2.0.0

## Examples

```
SELECT topology.TopoElementArray_Agg (ARRAY[e,t]) As tea
 FROM generate_series(1,3) As e CROSS JOIN generate_series(1,4) As t;
 tea

{{1,1},{1,2},{1,3},{1,4},{2,1},{2,2},{2,3},{2,4},{3,1},{3,2},{3,3},{3,4}}
```

## See Also

## 11.9 TopoGeometry Editors

### 11.9.1 clearTopoGeom

`clearTopoGeom` — Clears the content of a topo geometry

#### Synopsis

```
topogeometry clearTopoGeom(topogeometry topogeom);
```

#### Description

Clears the content a [TopoGeometry](#) turning it into an empty one. Mostly useful in conjunction with [toTopoGeom](#) to replace the shape of existing objects and any dependent object in higher hierarchical levels.

Availability: 2.1

#### Examples

```
-- Shrink all TopoGeometry polygons by 10 meters
UPDATE nei_topo SET topo = ST_Buffer(clearTopoGeom(topo), -10);
```

## See Also

[toTopoGeom](#)

### 11.9.2 TopoGeom\_addElement

`TopoGeom_addElement` — Add an element to the definition of a TopoGeometry

#### Synopsis

```
topogeometry TopoGeom_addElement(topogeometry tg, topoelement el);
```

---

## Description

Adds a **TopoElement** to the definition of a TopoGeometry object. Does not error out if the element is already part of the definition.

Availability: 2.3

## Examples

```
-- Add edge 5 to TopoGeometry tg
UPDATE mylayer SET tg = TopoGeom_addElement(tg, '{5,2}');
```

## See Also

[TopoGeom\\_remElement](#), [CreateTopoGeom](#)

### 11.9.3 TopoGeom\_remElement

**TopoGeom\_remElement** — Remove an element from the definition of a TopoGeometry

## Synopsis

topogeometry **TopoGeom\_remElement**(topogeometry tg, topelement el);

## Description

Removes a **TopoElement** from the definition of a TopoGeometry object.

Availability: 2.3

## Examples

```
-- Remove face 43 from TopoGeometry tg
UPDATE mylayer SET tg = TopoGeom_remElement(tg, '{43,3}');
```

## See Also

[TopoGeom\\_addElement](#), [CreateTopoGeom](#)

### 11.9.4 toTopoGeom

**toTopoGeom** — Adds a geometry shape to an existing topo geometry

## Description

Refer to [toTopoGeom](#)

---

## 11.10 TopoGeometry Accessors

### 11.10.1 GetTopoGeomElementArray

`GetTopoGeomElementArray` — Returns a `topoelementarray` (an array of `topoelements`) containing the topological elements and type of the given `TopoGeometry` (primitive elements)

#### Synopsis

```
topoelementarray GetTopoGeomElementArray(varchar toponame, integer layer_id, integer tg_id);
topoelementarray topoelement GetTopoGeomElementArray(topogeometry tg);
```

#### Description

Returns a [TopoElementArray](#) containing the topological elements and type of the given `TopoGeometry` (primitive elements). This is similar to `GetTopoGeomElements` except it returns the elements as an array rather than as a dataset.

`tg_id` is the topogeometry id of the topogeometry object in the topology in the layer denoted by `layer_id` in the `topology.layer` table.

Availability: 1.?

#### Examples

#### See Also

[GetTopoGeomElements](#), [TopoElementArray](#)

### 11.10.2 GetTopoGeomElements

`GetTopoGeomElements` — Returns a set of `topoelement` objects containing the topological `element_id`,`element_type` of the given `TopoGeometry` (primitive elements)

#### Synopsis

```
setof topoelement GetTopoGeomElements(varchar toponame, integer layer_id, integer tg_id);
setof topoelement GetTopoGeomElements(topogeometry tg);
```

#### Description

Returns a set of `element_id`,`element_type` (`topoelements`) for a given topogeometry object in `toponame` schema.

`tg_id` is the topogeometry id of the topogeometry object in the topology in the layer denoted by `layer_id` in the `topology.layer` table.

Availability: 2.0.0

#### Examples

## 11.11 TopoGeometry Outputs

### 11.11.1 AsGML

AsGML — Returns the GML representation of a topogeometry.

#### Synopsis

```
text AsGML(topogeometry tg);
text AsGML(topogeometry tg, text nsprefix_in);
text AsGML(topogeometry tg, regclass visitedTable);
text AsGML(topogeometry tg, regclass visitedTable, text nsprefix);
text AsGML(topogeometry tg, text nsprefix_in, integer precision, integer options);
text AsGML(topogeometry tg, text nsprefix_in, integer precision, integer options, regclass visitedTable);
text AsGML(topogeometry tg, text nsprefix_in, integer precision, integer options, regclass visitedTable, text idprefix);
text AsGML(topogeometry tg, text nsprefix_in, integer precision, integer options, regclass visitedTable, text idprefix, int gmlversion);
```

#### Description

Returns the GML representation of a topogeometry in version GML3 format. If no `nsprefix_in` is specified then `gml` is used. Pass in an empty string for `nsprefix` to get a non-qualified name space. The precision (default: 15) and options (default 1) parameters, if given, are passed untouched to the underlying call to `ST_AsGML`.

The `visitedTable` parameter, if given, is used for keeping track of the visited Node and Edge elements so to use cross-references (`xlink:xref`) rather than duplicating definitions. The table is expected to have (at least) two integer fields: `'element_type'` and `'element_id'`. The calling user must have both read and write privileges on the given table. For best performance, an index should be defined on `element_type` and `element_id`, in that order. Such index would be created automatically by adding a unique constraint to the fields. Example:

```
CREATE TABLE visited (
 element_type integer, element_id integer,
 unique(element_type, element_id)
);
```

The `idprefix` parameter, if given, will be prepended to Edge and Node tag identifiers.

The `gmlver` parameter, if given, will be passed to the underlying `ST_AsGML`. Defaults to 3.

Availability: 2.0.0

#### Examples

This uses the topo geometry we created in [CreateTopoGeom](#)

```
SELECT topology.AsGML(topo) As rdgml
FROM ri.roads
WHERE road_name = 'Unknown';

-- rdgml--
<gml:TopoCurve>
 <gml:directedEdge>
 <gml:Edge gml:id="E1">
 <gml:directedNode orientation="-">
 <gml:Node gml:id="N1"/>
 </gml:directedNode>
 </gml:directedEdge>
 </gml:TopoCurve>
```

```

 <gml:Curve srsName="urn:ogc:def:crs:EPSG::3438">

**11.11.2 AsTopoJSON**

AsTopoJSON — Returns the TopoJSON representation of a topogeometry.

**Synopsis**

```
text AsTopoJSON(topogeometry tg, regclass edgeMapTable);
```

**Description**

Returns the TopoJSON representation of a topogeometry. If `edgeMapTable` is not null, it will be used as a lookup/storage mapping of edge identifiers to arc indices. This is to be able to allow for a compact "arcs" array in the final document.

The table, if given, is expected to have an "arc\_id" field of type "serial" and an "edge\_id" of type integer; the code will query the table for "edge\_id" so it is recommended to add an index on that field.

**Note**

Arc indices in the TopoJSON output are 0-based but they are 1-based in the "edgeMapTable" table.

A full TopoJSON document will need to contain, in addition to the snippets returned by this function, the actual arcs plus some headers. See the [TopoJSON specification](#).

Availability: 2.1.0

Enhanced: 2.2.1 added support for puntal inputs

**See Also**

[ST\\_AsGeoJSON](#)

## Examples

```

CREATE TEMP TABLE edgemap(arc_id serial, edge_id int unique);

-- header
SELECT '{ "type": "Topology", "transform": { "scale": [1,1], "translate": [0,0] }, "objects ←
 ": {'

-- objects
UNION ALL SELECT '' || feature_name || ': ' || AsTopoJSON(feature, 'edgemap')
FROM features.big_parcel WHERE feature_name = 'P3P4';

-- arcs
WITH edges AS (
 SELECT m.arc_id, e.geom FROM edgemap m, city_data.edge e
 WHERE e.edge_id = m.edge_id
), points AS (
 SELECT arc_id, (st_dumppoints(geom)).* FROM edges
), compare AS (
 SELECT p2.arc_id,
 CASE WHEN p1.path IS NULL THEN p2.geom
 ELSE ST_Translate(p2.geom, -ST_X(p1.geom), -ST_Y(p1.geom))
 END AS geom
 FROM points p2 LEFT OUTER JOIN points p1
 ON (p1.arc_id = p2.arc_id AND p2.path[1] = p1.path[1]+1)
 ORDER BY arc_id, p2.path
), arcdump AS (
 SELECT arc_id, (regexp_matches(ST_AsGeoJSON(geom), '\[.*\]'))[1] as t
 FROM compare
), arcs AS (
 SELECT arc_id, '[' || array_to_string(array_agg(t), ',') || ']' as a FROM arcdump
 GROUP BY arc_id
 ORDER BY arc_id
)
SELECT '}', "arcs": [' UNION ALL
SELECT array_to_string(array_agg(a), E',\n') from arcs

-- footer
UNION ALL SELECT '}}'::text as t;

-- Result:
{ "type": "Topology", "transform": { "scale": [1,1], "translate": [0,0] }, "objects": {
"P3P4": { "type": "MultiPolygon", "arcs": [[[[-1]], [[6,5,-5,-4,-3,1]]]]
}, "arcs": [
[[25,30],[6,0],[0,10],[-14,0],[0,-10],[8,0]],
[[35,6],[0,8]],
[[35,6],[12,0]],
[[47,6],[0,8]],
[[47,14],[0,8]],
[[35,22],[12,0]],
[[35,14],[0,8]]
]]

```

## 11.12 Topology Spatial Relationships

### 11.12.1 Equals

Equals — Returns true if two topogeometries are composed of the same topology primitives.

## Synopsis

boolean **Equals**(topogeometry tg1, topogeometry tg2);

## Description

Returns true if two topogeometries are composed of the same topology primitives: faces, edges, nodes.

### Note

This function not supported for topogeometries that are geometry collections. It also can not compare topogeometries from different topologies.

Availability: 1.1.0

This function supports 3d and will not drop the z-index.

## Examples

## See Also

[GetTopoGeomElements](#), [ST\\_Equals](#)

## 11.12.2 Intersects

**Intersects** — Returns true if any pair of primitives from the two topogeometries intersect.

## Synopsis

boolean **Intersects**(topogeometry tg1, topogeometry tg2);

## Description

Returns true if any pair of primitives from the two topogeometries intersect.

### Note

This function not supported for topogeometries that are geometry collections. It also can not compare topogeometries from different topologies. Also not currently supported for hierarchichal topogeometries (topogeometries composed of other topogeometries).

Availability: 1.1.0

This function supports 3d and will not drop the z-index.

## Examples

## See Also

## Chapter 12

# Address Standardizer

This is a fork of the [PAGC standardizer](#) (original code for this portion was [PAGC PostgreSQL Address Standardizer](#)).

The address standardizer is a single line address parser that takes an input address and normalizes it based on a set of rules stored in a table and helper lex and gaz tables.

The code is built into a single postgresql extension library called `address_standardizer` which can be installed with `CREATE EXTENSION address_standardizer;`. In addition to the `address_standardizer` extension, a sample data extension called `address_standardizer_data_us` extensions is built, which contains `gaz`, `lex`, and `rules` tables for US data. This extensions can be installed via: `CREATE EXTENSION address_standardizer_data_us;`

The code for this extension can be found in the PostGIS `extensions/address_standardizer` and is currently self-contained.

For installation instructions refer to: [Section 2.7](#).

### 12.1 How the Parser Works

The parser works from right to left looking first at the macro elements for postcode, state/province, city, and then looks micro elements to determine if we are dealing with a house number street or intersection or landmark. It currently does not look for a country code or name, but that could be introduced in the future.

**Country code** Assumed to be US or CA based on: postcode as US or Canada state/province as US or Canada else US

**Postcode/zipcode** These are recognized using Perl compatible regular expressions. These regexs are currently in the `parseaddress-api.c` and are relatively simple to make changes to if needed.

**State/province** These are recognized using Perl compatible regular expressions. These regexs are currently in the `parseaddress-api.c` but could get moved into includes in the future for easier maintenance.

### 12.2 Address Standardizer Types

#### 12.2.1 stdaddr

`stdaddr` — A composite type that consists of the elements of an address. This is the return type for `standardize_address` function.

---

## Description

A composite type that consists of elements of an address. This is the return type for `standardize_address` function. Some descriptions for elements are borrowed from [PAGC Postal Attributes](#).

The token numbers denote the output reference number in the [rules table](#).

This method needs `address_standardizer` extension.

**building** is text (token number 0): Refers to building number or name. Unparsed building identifiers and types. Generally blank for most addresses.

**house\_num** is a text (token number 1): This is the street number on a street. Example *75* in *75 State Street*.

**preDir** is text (token number 2): STREET NAME PRE-DIRECTIONAL such as North, South, East, West etc.

**qual** is text (token number 3): STREET NAME PRE-MODIFIER Example *OLD* in *3715 OLD HIGHWAY 99*.

**preType** is text (token number 4): STREET PREFIX TYPE

**name** is text (token number 5): STREET NAME

**suftype** is text (token number 6): STREET POST TYPE e.g. St, Ave, Cir. A street type following the root street name. Example *STREET* in *75 State Street*.

**sufdir** is text (token number 7): STREET POST-DIRECTIONAL A directional modifier that follows the street name.. Example *WEST* in *3715 TENTH AVENUE WEST*.

**ruralroute** is text (token number 8): RURAL ROUTE . Example *8* in *RR 7*.

**extra** is text: Extra information like Floor number.

**city** is text (token number 10): Example Boston.

**state** is text (token number 11): Example MASSACHUSETTS

**country** is text (token number 12): Example USA

**postcode** is text POSTAL CODE (ZIP CODE) (token number 13): Example 02109

**box** is text POSTAL BOX NUMBER (token number 14 and 15): Example 02109

**unit** is text Apartment number or Suite Number (token number 17): Example *3B* in *APT 3B*.

## 12.3 Address Standardizer Tables

### 12.3.1 rules table

rules table — The rules table contains a set of rules that maps address input sequence tokens to standardized output sequence. A rule is defined as a set of input tokens followed by -1 (terminator) followed by set of output tokens followed by -1 followed by number denoting kind of rule followed by ranking of rule.

## Description

A rules table must have at least the following columns, though you are allowed to add more for your own uses.

**id** Primary key of table

**rule** text field denoting the rule. Details at [PAGC Address Standardizer Rule records](#).

A rule consists of a set of non-negative integers representing input tokens, terminated by a -1, followed by an equal number of non-negative integers representing postal attributes, terminated by a -1, followed by an integer representing a rule type, followed by an integer representing the rank of the rule. The rules are ranked from 0 (lowest) to 17 (highest).

So for example the rule 2 0 2 22 3 -1 5 5 6 7 3 -1 2 6 maps to sequence of output tokens *TYPE NUMBER TYPE DIRECT QUALIF* to the output sequence *STREET STREET SUFTYP SUFDIR QUALIF*. The rule is an ARC\_C rule of rank 6.

Numbers for corresponding output tokens are listed in [stdaddr](#).

## Input Tokens

Each rule starts with a set of input tokens followed by a terminator -1. Valid input tokens excerpted from [PAGC Input Tokens](#) are as follows:

### Form-Based Input Tokens

**AMPERS** (13). The ampersand (&) is frequently used to abbreviate the word "and".

**DASH** (9). A punctuation character.

**DOUBLE** (21). A sequence of two letters. Often used as identifiers.

**FRACT** (25). Fractions are sometimes used in civic numbers or unit numbers.

**MIXED** (23). An alphanumeric string that contains both letters and digits. Used for identifiers.

**NUMBER** (0). A string of digits.

**ORD** (15). Representations such as First or 1st. Often used in street names.

**ORD** (18). A single letter.

**WORD** (1). A word is a string of letters of arbitrary length. A single letter can be both a SINGLE and a WORD.

### Function-based Input Tokens

**BOXH** (14). Words used to denote post office boxes. For example *Box* or *PO Box*.

**BUILDH** (19). Words used to denote buildings or building complexes, usually as a prefix. For example: *Tower* in *Tower 7A*.

**BUILDT** (24). Words and abbreviations used to denote buildings or building complexes, usually as a suffix. For example: *Shopping Centre*.

**DIRECT** (22). Words used to denote directions, for example *North*.

**MILE** (20). Words used to denote milepost addresses.

**ROAD** (6). Words and abbreviations used to denote highways and roads. For example: the *Interstate* in *Interstate 5*

**RR** (8). Words and abbreviations used to denote rural routes. *RR*.

**TYPE** (2). Words and abbreviation used to denote street types. For example: *ST* or *AVE*.

**UNITH** (16). Words and abbreviation used to denote internal subaddresses. For example, *APT* or *UNIT*.

## Postal Type Input Tokens

**QUINT** (28). A 5 digit number. Identifies a Zip Code

**QUAD** (29). A 4 digit number. Identifies ZIP4.

**PCH** (27). A 3 character sequence of letter number letter. Identifies an FSA, the first 3 characters of a Canadian postal code.

**PCT** (26). A 3 character sequence of number letter number. Identifies an LDU, the last 3 characters of a Canadian postal code.

## Stopwords

STOPWORDS combine with WORDS. In rules a string of multiple WORDs and STOPWORDS will be represented by a single WORD token.

**STOPWORD** (7). A word with low lexical significance, that can be omitted in parsing. For example: *THE*.

## Output Tokens

After the first -1 (terminator), follows the output tokens and their order, followed by a terminator -1. Numbers for corresponding output tokens are listed in [stdaddr](#). What are allowed is dependent on kind of rule. Output tokens valid for each rule type are listed in the section called "[Rule Types and Rank](#)".

## Rule Types and Rank

The final part of the rule is the rule type which is denoted by one of the following, followed by a rule rank. The rules are ranked from 0 (lowest) to 17 (highest).

### MACRO\_C

(token number = "0"). The class of rules for parsing MACRO clauses such as *PLACE STATE ZIP*

**MACRO\_C output tokens** (excerpted from <http://www.pgcgeo.org/docs/html/pagc-12.html#--r-ty->).

**CITY** (token number "10"). Example "Albany"

**STATE** (token number "11"). Example "NY"

**NATION** (token number "12"). This attribute is not used in most reference files. Example "USA"

**POSTAL** (token number "13"). (SADS elements "ZIP CODE" , "PLUS 4" ). This attribute is used for both the US Zip and the Canadian Postal Codes.

### MICRO\_C

(token number = "1"). The class of rules for parsing full MICRO clauses (such as House, street, sufdir, predir, pretyp, suftype, qualif) (ie ARC\_C plus CIVIC\_C). These rules are not used in the build phase.

**MICRO\_C output tokens** (excerpted from <http://www.pgcgeo.org/docs/html/pagc-12.html#--r-ty->).

**HOUSE** is a text (token number 1): This is the street number on a street. Example 75 in 75 State Street.

**predir** is text (token number 2): STREET NAME PRE-DIRECTIONAL such as North, South, East, West etc.

**qual** is text (token number 3): STREET NAME PRE-MODIFIER Example *OLD* in 3715 OLD HIGHWAY 99.

**pretype** is text (token number 4): STREET PREFIX TYPE

**street** is text (token number 5): STREET NAME

**suftype** is text (token number 6): STREET POST TYPE e.g. St, Ave, Cir. A street type following the root street name. Example *STREET* in 75 State Street.

**sufdir** is text (token number 7): STREET POST-DIRECTIONAL A directional modifier that follows the street name.. Example *WEST* in 3715 TENTH AVENUE WEST.

### ARC\_C

(token number = "2"). The class of rules for parsing MICRO clauses, excluding the HOUSE attribute. As such uses same set of output tokens as MICRO\_C minus the HOUSE token.

### CIVIC\_C

(token number = "3"). The class of rules for parsing the HOUSE attribute.

### EXTRA\_C

(token number = "4"). The class of rules for parsing EXTRA attributes - attributes excluded from geocoding. These rules are not used in the build phase.

**EXTRA\_C output tokens** (excerpted from <http://www.pagcgeo.org/docs/html/pagc-12.html#-r-ty->).

**BLDNG** (token number 0): Unparsed building identifiers and types.

**BOXH** i(token number 14): The **BOX** in BOX 3B

**BOXT** (token number 15): The **3B** in BOX 3B

**RR** (token number 8): The **RR** in RR 7

**UNITH** (token number 16): The **APT** in APT 3B

**UNITT** (token number 17): The **3B** in APT 3B

**UNKNWN** (token number 9): An otherwise unclassified output.

## 12.3.2 lex table

lex table — A lex table is used to classify alphanumeric input and associate that input with (a) input tokens ( See the section called “**Input Tokens**”) and (b) standardized representations.

### Description

A lex (short for lexicon) table is used to classify alphanumeric input and associate that input with the section called “**Input Tokens**” and (b) standardized representations. Things you will find in these tables are ONE mapped to stdword: 1.

A lex has at least the following columns in the table. You may add

**id** Primary key of table

**seq** integer: definition number?

**word** text: the input word

**stdword** text: the standardized replacement word

**token** integer: the kind of word it is. Only if it is used in this context will it be replaced. Refer to **PAGC Tokens**.

## 12.3.3 gaz table

gaz table — A gaz table is used to standardize place names and associate that input with (a) input tokens ( See the section called “**Input Tokens**”) and (b) standardized representations.

**Description**

A gaz (short for gazeteer) table is used to classify place names and associate that input with the section called “**Input Tokens**” and (b) standardized representations. For example if you are in US, you may load these with State Names and associated abbreviations.

A gaz table has at least the following columns in the table. You may add more columns if you wish for your own purposes.

**id** Primary key of table

**seq** integer: definition number? - identifier used for that instance of the word

**word** text: the input word

**stdword** text: the standardized replacement word

**token** integer: the kind of word it is. Only if it is used in this context will it be replaced. Refer to [PAGC Tokens](#).

## 12.4 Address Standardizer Functions

### 12.4.1 parse\_address

parse\_address — Takes a 1 line address and breaks into parts

**Synopsis**

```
record parse_address(text address);
```

**Description**

Returns takes as input an address, and returns a record output consisting of fields *num*, *street*, *street2*, *address1*, *city*, *state*, *zip*, *zipplus*, *country*.

Availability: 2.2.0

This method needs address\_standardizer extension.

**Examples****Single Address**

```
SELECT num, street, city, zip, zipplus
FROM parse_address('1 Devonshire Place, Boston, MA 02109-1234') AS a;
```

num	street	city	zip	zipplus
1	Devonshire Place	Boston	02109	1234

**Table of addresses**

```
-- basic table
CREATE TABLE places(addid serial PRIMARY KEY, address text);

INSERT INTO places(address)
VALUES ('529 Main Street, Boston MA, 02129'),
('77 Massachusetts Avenue, Cambridge, MA 02139'),
```

```

('25 Wizard of Oz, Walaford, KS 99912323'),
('26 Capen Street, Medford, MA'),
('124 Mount Auburn St, Cambridge, Massachusetts 02138'),
('950 Main Street, Worcester, MA 01610');

-- parse the addresses
-- if you want all fields you can use (a).*
SELECT addid, (a).num, (a).street, (a).city, (a).state, (a).zip, (a).zipplus
FROM (SELECT addid, parse_address(address) As a
FROM places) AS p;

```

addid	num	street	city	state	zip	zipplus
1	529	Main Street	Boston	MA	02129	
2	77	Massachusetts Avenue	Cambridge	MA	02139	
3	25	Wizard of Oz	Walaford	KS	99912	323

### 12.4.2 standardize\_address

`standardize_address` — Returns an `stdaddr` form of an input address utilizing `lex`, `gaz`, and `rule` tables.

#### Synopsis

```

stdaddr standardize_address(text lextab, text gaztab, text rultab, text address);
stdaddr standardize_address(text lextab, text gaztab, text rultab, text micro, text macro);

```

#### Description

Returns an `stdaddr` form of an input address utilizing `lex table` table name, `gaz table`, and `rules table` table names and an address.

Variant 1: Takes an address as a single line.

Variant 2: Takes an address as 2 parts. A `micro` consisting of standard first line of postal address e.g. `house_num street`, and a `macro` consisting of standard postal second line of an address e.g. `city, state postal_code country`.

Availability: 2.2.0

This method needs `address_standardizer` extension.

#### Examples

Using `address_standardizer_data_us` extension

```
CREATE EXTENSION address_standardizer_data_us; -- only needs to be done once
```

Variant 1: Single line address. This doesn't work well with non-US addresses

```

SELECT house_num, name, suftype, city, country, state, unit FROM standardize_address(' ←
us_lex',
 'us_gaz', 'us_rules', 'One Devonshire Place, PH 301, Boston, MA 02109');

```

house_num	name	suftype	city	country	state	unit
1	DEVONSHIRE	PLACE	BOSTON	USA	MASSACHUSETTS	# PENTHOUSE 301

Using tables packaged with tiger geocoder. This example only works if you installed `postgis_tiger_geocoder`.

```
SELECT * FROM standardize_address('tiger.pagc_lex',
 'tiger.pagc_gaz', 'tiger.pagc_rules', 'One Devonshire Place, PH 301, Boston, MA ←
 02109-1234');
```

Make easier to read we'll dump output using `hstore` extension `CREATE EXTENSION hstore;` you need to install

```
SELECT (each(hstore(p))).*
FROM standardize_address('tiger.pagc_lex', 'tiger.pagc_gaz',
 'tiger.pagc_rules', 'One Devonshire Place, PH 301, Boston, MA 02109') As p;
```

key	value
box	
city	BOSTON
name	DEVONSHIRE
qual	
unit	# PENTHOUSE 301
extra	
state	MA
predir	
sufdir	
country	USA
pretype	
suftype	PL
building	
postcode	02109
house_num	1
ruralroute	

(16 rows)

**Variant 2: As a two part Address**

```
SELECT (each(hstore(p))).*
FROM standardize_address('tiger.pagc_lex', 'tiger.pagc_gaz',
 'tiger.pagc_rules', 'One Devonshire Place, PH 301', 'Boston, MA 02109, US') As p;
```

key	value
box	
city	BOSTON
name	DEVONSHIRE
qual	
unit	# PENTHOUSE 301
extra	
state	MA
predir	
sufdir	
country	USA
pretype	
suftype	PL
building	
postcode	02109
house_num	1
ruralroute	

(16 rows)

## Chapter 13

# PostGIS Extras

This chapter documents features found in the extras folder of the PostGIS source tarballs and source repository. These are not always packaged with PostGIS binary releases, but are usually plpgsql based or standard shell scripts that can be run as is.

### 13.1 Tiger Geocoder

There are a couple other open source geocoders for PostGIS, that unlike tiger geocoder have the advantage of multi-country geocoding support

- **Nominatim** uses OpenStreetMap gazeteer formatted data. It requires osm2pgsql for loading the data, PostgreSQL 8.4+ and PostGIS 1.5+ to function. It is packaged as a webservice interface and seems designed to be called as a webservice. Just like the tiger geocoder, it has both a geocoder and a reverse geocoder component. From the documentation, it is unclear if it has a pure SQL interface like the tiger geocoder, or if a good deal of the logic is implemented in the web interface.
- **GIS Graphy** also utilizes PostGIS and like Nominatim works with OpenStreetMap (OSM) data. It comes with a loader to load OSM data and similar to Nominatim is capable of geocoding not just US. Much like Nominatim, it runs as a webservice and relies on Java 1.5, Servlet apps, Solr. GisGraphy is cross-platform and also has a reverse geocoder among some other neat features.

#### 13.1.1 Drop\_Indexes\_Generate\_Script

`Drop_Indexes_Generate_Script` — Generates a script that drops all non-primary key and non-unique indexes on tiger schema and user specified schema. Defaults schema to `tiger_data` if no schema is specified.

##### Synopsis

```
text Drop_Indexes_Generate_Script(text param_schema=tiger_data);
```

##### Description

Generates a script that drops all non-primary key and non-unique indexes on tiger schema and user specified schema. Defaults schema to `tiger_data` if no schema is specified.

This is useful for minimizing index bloat that may confuse the query planner or take up unnecessary space. Use in combination with **Install\_Missing\_Indexes** to add just the indexes used by the geocoder.

Availability: 2.0.0

---

## Examples

```
SELECT drop_indexes_generate_script() As actionsql;
actionsql

DROP INDEX tiger.idx_tiger_countysub_lookup_lower_name;
DROP INDEX tiger.idx_tiger_edges_countyfp;
DROP INDEX tiger.idx_tiger_faces_countyfp;
DROP INDEX tiger.tiger_place_the_geom_gist;
DROP INDEX tiger.tiger_edges_the_geom_gist;
DROP INDEX tiger.tiger_state_the_geom_gist;
DROP INDEX tiger.idx_tiger_addr_least_address;
DROP INDEX tiger.idx_tiger_addr_tlid;
DROP INDEX tiger.idx_tiger_addr_zip;
DROP INDEX tiger.idx_tiger_county_countyfp;
DROP INDEX tiger.idx_tiger_county_lookup_lower_name;
DROP INDEX tiger.idx_tiger_county_lookup_snd_name;
DROP INDEX tiger.idx_tiger_county_lower_name;
DROP INDEX tiger.idx_tiger_county_snd_name;
DROP INDEX tiger.idx_tiger_county_the_geom_gist;
DROP INDEX tiger.idx_tiger_countysub_lookup_snd_name;
DROP INDEX tiger.idx_tiger_cousub_countyfp;
DROP INDEX tiger.idx_tiger_cousub_cousubfp;
DROP INDEX tiger.idx_tiger_cousub_lower_name;
DROP INDEX tiger.idx_tiger_cousub_snd_name;
DROP INDEX tiger.idx_tiger_cousub_the_geom_gist;
DROP INDEX tiger_data.idx_tiger_data_ma_addr_least_address;
DROP INDEX tiger_data.idx_tiger_data_ma_addr_tlid;
DROP INDEX tiger_data.idx_tiger_data_ma_addr_zip;
DROP INDEX tiger_data.idx_tiger_data_ma_county_countyfp;
DROP INDEX tiger_data.idx_tiger_data_ma_county_lookup_lower_name;
DROP INDEX tiger_data.idx_tiger_data_ma_county_lookup_snd_name;
DROP INDEX tiger_data.idx_tiger_data_ma_county_lower_name;
DROP INDEX tiger_data.idx_tiger_data_ma_county_snd_name;
:
:
```

### 13.1.2 Drop\_Nation\_Tables\_Generate\_Script

`Drop_Nation_Tables_Generate_Script` — Generates a script that drops all tables in the specified schema that start with `county_all`, `state_all` or state code followed by `county` or `state`.

#### Synopsis

```
text Drop_Nation_Tables_Generate_Script(text param_schema=tiger_data);
```

#### Description

Generates a script that drops all tables in the specified schema that start with `county_all`, `state_all` or stae code followed by `county` or `state`. This is needed if you are upgrading from `tiger_2010` to `tiger_2011` data.

Availability: 2.1.0

## Examples

```
SELECT drop_nation_tables_generate_script();
DROP TABLE tiger_data.county_all;
DROP TABLE tiger_data.county_all_lookup;
DROP TABLE tiger_data.state_all;
DROP TABLE tiger_data.ma_county;
DROP TABLE tiger_data.ma_state;
```

## See Also

[Loader\\_Generate\\_Nation\\_Script](#)

### 13.1.3 Drop\_State\_Tables\_Generate\_Script

**Drop\_State\_Tables\_Generate\_Script** — Generates a script that drops all tables in the specified schema that are prefixed with the state abbreviation. Defaults schema to `tiger_data` if no schema is specified.

## Synopsis

```
text Drop_State_Tables_Generate_Script(text param_state, text param_schema=tiger_data);
```

## Description

Generates a script that drops all tables in the specified schema that are prefixed with the state abbreviation. Defaults schema to `tiger_data` if no schema is specified. This function is useful for dropping tables of a state just before you reload a state in case something went wrong during your previous load.

Availability: 2.0.0

## Examples

```
SELECT drop_state_tables_generate_script('PA');
DROP TABLE tiger_data.pa_addr;
DROP TABLE tiger_data.pa_county;
DROP TABLE tiger_data.pa_county_lookup;
DROP TABLE tiger_data.pa_cousub;
DROP TABLE tiger_data.pa_edges;
DROP TABLE tiger_data.pa_faces;
DROP TABLE tiger_data.pa_featnames;
DROP TABLE tiger_data.pa_place;
DROP TABLE tiger_data.pa_state;
DROP TABLE tiger_data.pa_zip_lookup_base;
DROP TABLE tiger_data.pa_zip_state;
DROP TABLE tiger_data.pa_zip_state_loc;
```

## See Also

---

### 13.1.4 Geocode

Geocode — Takes in an address as a string (or other normalized address) and outputs a set of possible locations which include a point geometry in NAD 83 long lat, a normalized address for each, and the rating. The lower the rating the more likely the match. Results are sorted by lowest rating first. Can optionally pass in maximum results, defaults to 10, and restrict\_region (defaults to NULL)

#### Synopsis

setof record **geocode**(varchar address, integer max\_results=10, geometry restrict\_region=NULL, norm\_addy OUT addy, geometry OUT geomout, integer OUT rating);

setof record **geocode**(norm\_addy in\_addy, integer max\_results=10, geometry restrict\_region=NULL, norm\_addy OUT addy, geometry OUT geomout, integer OUT rating);

#### Description

Takes in an address as a string (or already normalized address) and outputs a set of possible locations which include a point geometry in NAD 83 long lat, a `normalized_address` (addy) for each, and the rating. The lower the rating the more likely the match. Results are sorted by lowest rating first. Uses Tiger data (edges,faces,addr), PostgreSQL fuzzy string matching (soundex,levenshtein) and PostGIS line interpolation functions to interpolate address along the Tiger edges. The higher the rating the less likely the geocode is right. The geocoded point is defaulted to offset 10 meters from center-line off to side (L/R) of street address is located on.

Enhanced: 2.0.0 to support Tiger 2010 structured data and revised some logic to improve speed, accuracy of geocoding, and to offset point from centerline to side of street address is located on. The new parameter `max_results` useful for specifying number of best results or just returning the best result.

#### Examples: Basic

The below examples timings are on a 3.0 GHZ single processor Windows 7 machine with 2GB ram running PostgreSQL 9.1rc1/PostGIS 2.0 loaded with all of MA,MN,CA, RI state Tiger data loaded.

Exact matches are faster to compute (61ms)

```
SELECT g.rating, ST_X(g.geomout) As lon, ST_Y(g.geomout) As lat,
 (addy).address As stno, (addy).streetname As street,
 (addy).streettypeabbrev As styp, (addy).location As city, (addy).stateabbrev As st, (←
 addy).zip
FROM geocode('75 State Street, Boston MA 02109') As g;
```

rating	lon	lat	stno	street	styp	city	st	zip
0	-71.0556722990239	42.3589914927049	75	State	St	Boston	MA	02109

Even if zip is not passed in the geocoder can guess (took about 122-150 ms)

```
SELECT g.rating, ST_AsText(ST_SnapToGrid(g.geomout,0.00001)) As wktlonlat,
 (addy).address As stno, (addy).streetname As street,
 (addy).streettypeabbrev As styp, (addy).location As city, (addy).stateabbrev As st, (←
 addy).zip
FROM geocode('226 Hanover Street, Boston, MA',1) As g;
```

rating	wktlonlat	stno	street	styp	city	st	zip
1	POINT(-71.05528 42.36316)	226	Hanover	St	Boston	MA	02113

Can handle misspellings and provides more than one possible solution with ratings and takes longer (500ms).

```
SELECT g.rating, ST_AsText(ST_SnapToGrid(g.geomout,0.00001)) As wktmlonlat,
 (addy).address As stno, (addy).streetname As street,
 (addy).streettypeabbrev As styp, (addy).location As city, (addy).stateabbrev As st, (←
 addy).zip
FROM geocode('31 - 37 Stewart Street, Boston, MA 02116') As g;
rating | wktmlonlat | stno | street | styp | city | st | zip
-----+-----+-----+-----+-----+-----+-----+-----
70 | POINT(-71.06459 42.35113) | 31 | Stuart | St | Boston | MA | 02116
```

Using to do a batch geocode of addresses. Easiest is to set max\_results=1. Only process those not yet geocoded (have no rating).

```
CREATE TABLE addresses_to_geocode(addyid serial PRIMARY KEY, address text,
 lon numeric, lat numeric, new_address text, rating integer);

INSERT INTO addresses_to_geocode(address)
VALUES ('529 Main Street, Boston MA, 02129'),
 ('77 Massachusetts Avenue, Cambridge, MA 02139'),
 ('25 Wizard of Oz, Walaford, KS 99912323'),
 ('26 Capen Street, Medford, MA'),
 ('124 Mount Auburn St, Cambridge, Massachusetts 02138'),
 ('950 Main Street, Worcester, MA 01610');

-- only update the first 3 addresses (323-704 ms - there are caching and shared memory ←
-- effects so first geocode you do is always slower) --
-- for large numbers of addresses you don't want to update all at once
-- since the whole geocode must commit at once
-- For this example we rejoin with LEFT JOIN
-- and set to rating to -1 rating if no match
-- to ensure we don't regeocode a bad address
UPDATE addresses_to_geocode
 SET (rating, new_address, lon, lat)
 = (COALESCE((g.geo).rating,-1), pprint_addy((g.geo).addy),
 ST_X((g.geo).geomout)::numeric(8,5), ST_Y((g.geo).geomout)::numeric(8,5))
FROM (SELECT addyid
 FROM addresses_to_geocode
 WHERE rating IS NULL ORDER BY addyid LIMIT 3) As a
LEFT JOIN (SELECT addyid, (geocode(address,1)) As geo
 FROM addresses_to_geocode As ag
 WHERE ag.rating IS NULL ORDER BY addyid LIMIT 3) As g ON a.addyid = g.addyid
WHERE a.addyid = addresses_to_geocode.addyid;

result

Query returned successfully: 3 rows affected, 480 ms execution time.
```

```
SELECT * FROM addresses_to_geocode WHERE rating is not null;

addyid | address | lon | lat | ←
-----+-----+-----+-----+-----
1 | 529 Main Street, Boston MA, 02129 | -71.07181 | 42.38359 | 529 Main St, ←
 | Boston, MA 02129 | 0
2 | 77 Massachusetts Avenue, Cambridge, MA 02139 | -71.09428 | 42.35988 | 77 ←
 | Massachusetts Ave, Cambridge, MA 02139 | 0
3 | 25 Wizard of Oz, Walaford, KS 99912323 | | | ←
 | | -1
```

**Examples: Using Geometry filter**

```
SELECT g.rating, ST_AsText(ST_SnapToGrid(g.geomout,0.00001)) As wktlonlat,
 (addy).address As stno, (addy).streetname As street,
 (addy).streettypeabbrev As styp,
 (addy).location As city, (addy).stateabbrev As st, (addy).zip
FROM geocode('100 Federal Street, MA',
 3,
 (SELECT ST_Union(the_geom)
 FROM place WHERE statefp = '25' AND name = 'Lynn')::geometry
) As g;
```

rating	wktlonlat	stno	street	styp	city	st	zip
8	POINT(-70.96796 42.4659)	100	Federal	St	Lynn	MA	01905

Total query runtime: 245 ms.

**13.1.5 Geocode\_Intersection**

**Geocode\_Intersection** — Takes in 2 streets that intersect and a state, city, zip, and outputs a set of possible locations on the first cross street that is at the intersection, also includes a geomout as the point location in NAD 83 long lat, a `normalized_address` (addy) for each location, and the rating. The lower the rating the more likely the match. Results are sorted by lowest rating first. Can optionally pass in maximum results, defaults to 10. Uses Tiger data (edges, faces, addr), PostgreSQL fuzzy string matching (soundex, levenshtein).

**Synopsis**

```
setof record geocode_intersection(text roadway1, text roadway2, text in_state, text in_city, text in_zip, integer num_results=10,
norm_addy OUT addy, geometry OUT geomout, integer OUT rating);
```

**Description**

Takes in 2 streets that intersect and a state, city, zip, and outputs a set of possible locations on the first cross street that is at the intersection, also includes a point geometry in NAD 83 long lat, a normalized address for each location, and the rating. The lower the rating the more likely the match. Results are sorted by lowest rating first. Can optionally pass in maximum results, defaults to 10. Returns `normalized_address` (addy) for each, geomout as the point location in nad 83 long lat, and the rating. The lower the rating the more likely the match. Results are sorted by lowest rating first. Uses Tiger data (edges,faces,addr), PostgreSQL fuzzy string matching (soundex,levenshtein)

Availability: 2.0.0

**Examples: Basic**

The below examples timings are on a 3.0 GHZ single processor Windows 7 machine with 2GB ram running PostgreSQL 9.0/PostGIS 1.5 loaded with all of MA state Tiger data loaded. Currently a bit slow (3000 ms)

Testing on Windows 2003 64-bit 8GB on PostGIS 2.0 PostgreSQL 64-bit Tiger 2011 data loaded -- (41ms)

```
SELECT pprint_addy(addy), st_astext(geomout), rating
FROM geocode_intersection('Haverford St', 'Germania St', 'MA', 'Boston', ←
 '02130', 1);
```

pprint_addy	st_astext	rating
98 Haverford St, Boston, MA 02130	POINT(-71.101375 42.31376)	0

Even if zip is not passed in the geocoder can guess (took about 3500 ms on the windows 7 box), on the windows 2003 64-bit 741 ms

```
SELECT pprint_addy(addy), st_astext(geomout),rating
 FROM geocode_intersection('Weld', 'School', 'MA', 'Boston');
 pprint_addy | st_astext | rating
-----+-----+-----
 98 Weld Ave, Boston, MA 02119 | POINT(-71.099 42.314234) | 3
 99 Weld Ave, Boston, MA 02119 | POINT(-71.099 42.314234) | 3
```

**13.1.6 Get\_Geocode\_Setting**

Get\_Geocode\_Setting — Returns value of specific setting stored in tiger.geocode\_settings table.

**Synopsis**

text **Get\_Geocode\_Setting**(text setting\_name);

**Description**

Returns value of specific setting stored in tiger.geocode\_settings table. Settings allow you to toggle debugging of functions. Later plans will be to control rating with settings. Current list of settings are as follows:

name	setting	unit	category	↔	short_desc
debug_geocode_address	false	boolean	debug		outputs debug information ↔ in notice log such as queries when geocode_address is called if true
debug_geocode_intersection	false	boolean	debug		outputs debug information ↔ in notice log such as queries when geocode_intersection is called if true
debug_normalize_address	false	boolean	debug		outputs debug information ↔ in notice log such as queries and intermediate expressions when normalize_address is ↔ called if true
debug_reverse_geocode	false	boolean	debug		if true, outputs debug ↔ information in notice log such as queries and intermediate expressions when ↔ reverse_geocode
reverse_geocode_numbered_roads	0	integer	rating		For state and county ↔ highways, 0 - no preference in name, 1 - prefer the numbered ↔ highway name, 2 - ↔ prefer local state/ ↔ county name
use_pagc_address_parser	false	boolean	normalize		If set to true, will try ↔ to use the address_standardizer extension (via pagc_normalize_address) instead of tiger ↔ normalize_address built ↔ one

Changed: 2.2.0 : default settings are now kept in a table called `geocode_settings_default`. Use customized settingsa are in `geocode_settings` and only contain those that have been set by user.

Availability: 2.1.0

### Example return debugging setting

```
SELECT get_geocode_setting('debug_geocode_address') As result;
result

false
```

### See Also

[Set\\_Geocode\\_Setting](#)

## 13.1.7 Get\_Tract

`Get_Tract` — Returns census tract or field from tract table of where the geometry is located. Default to returning short name of tract.

### Synopsis

```
text get_tract(geometry loc_geom, text output_field=name);
```

### Description

Given a geometry will return the census tract location of that geometry. NAD 83 long lat is assumed if no spatial ref sys is specified.

Availability: 2.0.0

### Examples: Basic

```
SELECT get_tract(ST_Point(-71.101375, 42.31376)) As tract_name;
tract_name

1203.01
```

```
--this one returns the tiger geoid
SELECT get_tract(ST_Point(-71.101375, 42.31376), 'tract_id') As tract_id;
tract_id

25025120301
```

### See Also

[Geocode](#)>

## 13.1.8 Install\_Missing\_Indexes

`Install_Missing_Indexes` — Finds all tables with key columns used in geocoder joins and filter conditions that are missing used indexes on those columns and will add them.

## Synopsis

```
boolean Install_Missing_Indexes();
```

## Description

Finds all tables in `tiger` and `tiger_data` schemas with key columns used in geocoder joins and filters that are missing indexes on those columns and will output the SQL DDL to define the index for those tables and then execute the generated script. This is a helper function that adds new indexes needed to make queries faster that may have been missing during the load process. This function is a companion to [Missing\\_Indexes\\_Generate\\_Script](#) that in addition to generating the create index script, also executes it. It is called as part of the `update_geocode.sql` upgrade script.

Availability: 2.0.0

## Examples

```
SELECT install_missing_indexes();
 install_missing_indexes

t
```

## See Also

[Loader\\_Generate\\_Script](#), [Missing\\_Indexes\\_Generate\\_Script](#)

### 13.1.9 Loader\_Generate\_Census\_Script

`Loader_Generate_Census_Script` — Generates a shell script for the specified platform for the specified states that will download Tiger census state tract, bg, and tabblocks data tables, stage and load into `tiger_data` schema. Each state script is returned as a separate record.

## Synopsis

```
setof text loader_generate_census_script(text[] param_states, text os);
```

## Description

Generates a shell script for the specified platform for the specified states that will download Tiger data census state `tract`, block groups `bg`, and `tabblocks` data tables, stage and load into `tiger_data` schema. Each state script is returned as a separate record.

It uses `unzip` on Linux (7-zip on Windows by default) and `wget` to do the downloading. It uses [Section 4.4.2](#) to load in the data. Note the smallest unit it does is a whole state. It will only process the files in the staging and temp folders.

It uses the following control tables to control the process and different OS shell syntax variations.

1. `loader_variables` keeps track of various variables such as census site, year, data and staging schemas
2. `loader_platform` profiles of various platforms and where the various executables are located. Comes with windows and linux. More can be added.
3. `loader_lookuptables` each record defines a kind of table (state, county), whether to process records in it and how to load them in. Defines the steps to import data, stage data, add, removes columns, indexes, and constraints for each. Each table is prefixed with the state and inherits from a table in the `tiger` schema. e.g. creates `tiger_data.ma_faces` which inherits from `tiger.faces`

Availability: 2.0.0

#### Note

**Loader\_Generate\_Script** includes this logic, but if you installed tiger geocoder prior to PostGIS 2.0.0 alpha5, you'll need to run this on the states you have already done to get these additional tables.

## Examples

Generate script to load up data for select states in Windows shell script format.

```
SELECT loader_generate_census_script (ARRAY['MA'], 'windows');
-- result --

### 13.1.10 Loader\_Generate\_Script

`Loader_Generate_Script` — Generates a shell script for the specified platform for the specified states that will download Tiger data, stage and load into `tiger_data` schema. Each state script is returned as a separate record. Latest version supports Tiger 2010 structural changes and also loads census tract, block groups, and blocks tables.

#### Synopsis

```
setof text loader_generate_script(text[] param_states, text os);
```

#### Description

Generates a shell script for the specified platform for the specified states that will download Tiger data, stage and load into `tiger_data` schema. Each state script is returned as a separate record.

It uses `unzip` on Linux (7-zip on Windows by default) and `wget` to do the downloading. It uses Section 4.4.2 to load in the data. Note the smallest unit it does is a whole state, but you can overwrite this by downloading the files yourself. It will only process the files in the staging and temp folders.

It uses the following control tables to control the process and different OS shell syntax variations.

1. `loader_variables` keeps track of various variables such as census site, year, data and staging schemas
2. `loader_platform` profiles of various platforms and where the various executables are located. Comes with windows and linux. More can be added.
3. `loader_lookuptables` each record defines a kind of table (state, county), whether to process records in it and how to load them in. Defines the steps to import data, stage data, add, removes columns, indexes, and constraints for each. Each table is prefixed with the state and inherits from a table in the tiger schema. e.g. creates `tiger_data.ma_faces` which inherits from `tiger.faces`

Availability: 2.0.0 to support Tiger 2010 structured data and load census tract (tract), block groups (bg), and blocks (tabblocks) tables .

#### Note

If you are using pgAdmin 3, be warned that by default pgAdmin 3 truncates long text. To fix, change *File -> Options -> Query Tool -> Query Editor -> Max. characters per column* to larger than 50000 characters.

## Examples

Using `psql` where `gistest` is your database and `/gisdata/data_load.sh` is the file to create with the shell commands to run.

```
psql -U postgres -h localhost -d gistest -A -t \
-c "SELECT Loader_Generate_Script (ARRAY['MA'], 'gistest')" > /gisdata/data_load.sh;
```

Generate script to load up data for 2 states in Windows shell script format.

```
SELECT loader_generate_script (ARRAY['MA','RI'], 'windows') AS result;
-- result --
set TMPDIR=\gisdata\temp\
set UNZIPTOOL="C:\Program Files\7-Zip\7z.exe"
set WGETTOOL="C:\wget\wget.exe"
set PGBIN=C:\Program Files\PostgreSQL\9.4\bin\
set PGPORT=5432
set PGHOST=localhost
set PGUSER=postgres
set PGPASSWORD=yourpasswordhere
set PGDATABASE=geocoder
set PSQL="%PGBIN%psql"
set SHP2PGSQL="%PGBIN%shp2pgsql"
cd \gisdata

cd \gisdata
%WGETTOOL% ftp://ftp2.census.gov/geo/tiger/TIGER2015/PLACE/tl_*_25_* --no-parent --relative ←
--recursive --level=2 --accept=zip --mirror --reject=html
cd \gisdata/ftp2.census.gov/geo/tiger/TIGER2015/PLACE
:
:
```

Generate sh script

```
SELECT loader_generate_script (ARRAY['MA','RI'], 'sh') AS result;
-- result --
TMPDIR="/gisdata/temp/"
UNZIPTOOL=unzip

Section 2.8.1, [Loader\\_Generate\\_Nation\\_Script](#)

### 13.1.11 Loader\_Generate\_Nation\_Script

`Loader_Generate_Nation_Script` — Generates a shell script for the specified platform that loads in the county and state lookup tables.

#### Synopsis

```
text loader_generate_nation_script(text os);
```

#### Description

Generates a shell script for the specified platform that loads in the `county_all`, `county_all_lookup`, `state_all` tables into `tiger_data` schema. These inherit respectively from the `county`, `county_lookup`, `state` tables in `tiger` schema.

It uses `unzip` on Linux (7-zip on Windows by default) and `wget` to do the downloading. It uses Section 4.4.2 to load in the data.

It uses the following control tables `tiger.loader_platform`, `tiger.loader_variables`, and `tiger.loader_lookupables` to control the process and different OS shell syntax variations.

1. `loader_variables` keeps track of various variables such as census site, year, data and staging schemas
2. `loader_platform` profiles of various platforms and where the various executables are located. Comes with windows and linux/unix. More can be added.
3. `loader_lookupables` each record defines a kind of table (state, county), whether to process records in it and how to load them in. Defines the steps to import data, stage data, add, removes columns, indexes, and constraints for each. Each table is prefixed with the state and inherits from a table in the tiger schema. e.g. creates `tiger_data.ma_faces` which inherits from `tiger.faces`

Availability: 2.1.0

#### Note

If you were running `tiger_2010` version and you want to reload as state with `tiger_2011`, you'll need to for the very first load generate and run drop statements [Drop\\_Nation\\_Tables\\_Generate\\_Script](#) before you run this script.

#### Examples

Generate script script to load nation data Windows.

```
SELECT loader_generate_nation_script('windows');
```

Generate script to load up data for Linux/Unix systems.

```
SELECT loader_generate_nation_script('sh');
```

### 13.1.12 Missing\_Indexes\_Generate\_Script

`Missing_Indexes_Generate_Script` — Finds all tables with key columns used in geocoder joins that are missing indexes on those columns and will output the SQL DDL to define the index for those tables.

## Synopsis

```
text Missing_Indexes_Generate_Script();
```

## Description

Finds all tables in `tiger` and `tiger_data` schemas with key columns used in geocoder joins that are missing indexes on those columns and will output the SQL DDL to define the index for those tables. This is a helper function that adds new indexes needed to make queries faster that may have been missing during the load process. As the geocoder is improved, this function will be updated to accommodate new indexes being used. If this function outputs nothing, it means all your tables have what we think are the key indexes already in place.

Availability: 2.0.0

## Examples

```
SELECT missing_indexes_generate_script();
-- output: This was run on a database that was created before many corrections were made to ←
the loading script ---
CREATE INDEX idx_tiger_county_countyfp ON tiger.county USING btree(countyfp);
CREATE INDEX idx_tiger_cousub_countyfp ON tiger.cousub USING btree(countyfp);
CREATE INDEX idx_tiger_edges_tfidr ON tiger.edges USING btree(tfidr);
CREATE INDEX idx_tiger_edges_tfidl ON tiger.edges USING btree(tfidl);
CREATE INDEX idx_tiger_zip_lookup_all_zip ON tiger.zip_lookup_all USING btree(zip);
CREATE INDEX idx_tiger_data_ma_county_countyfp ON tiger_data.ma_county USING btree(countyfp ←
);
CREATE INDEX idx_tiger_data_ma_cousub_countyfp ON tiger_data.ma_cousub USING btree(countyfp ←
);
CREATE INDEX idx_tiger_data_ma_edges_countyfp ON tiger_data.ma_edges USING btree(countyfp);
CREATE INDEX idx_tiger_data_ma_faces_countyfp ON tiger_data.ma_faces USING btree(countyfp);
```

### 13.1.13 Normalize\_Address

`Normalize_Address` — Given a textual street address, returns a composite `norm_addy` type that has road suffix, prefix and type standardized, street, streetname etc. broken into separate fields. This function will work with just the lookup data packaged with the `tiger_geocoder` (no need for `tiger` census data).

## Synopsis

```
norm_addy normalize_address(varchar in_address);
```

## Description

Given a textual street address, returns a composite `norm_addy` type that has road suffix, prefix and type standardized, street, streetname etc. broken into separate fields. This is the first step in the geocoding process to get all addresses into normalized postal form. No other data is required aside from what is packaged with the geocoder.

This function just uses the various direction/state/suffix lookup tables preloaded with the `tiger_geocoder` and located in the `tiger` schema, so it doesn't need you to download `tiger` census data or any other additional data to make use of it. You may find the need to add more abbreviations or alternative namings to the various lookup tables in the `tiger` schema.

It uses various control lookup tables located in `tiger` schema to normalize the input address.

Fields in the `norm_addy` type object returned by this function in this order where () indicates a field required by the geocoder, [] indicates an optional field:

(address) [predirAbbrev] (streetName) [streetTypeAbbrev] [postdirAbbrev] [internal] [location] [stateAbbrev] [zip]

1. `address` is an integer: The street number
2. `predirAbbrev` is varchar: Directional prefix of road such as N, S, E, W etc. These are controlled using the `direction_lookup` table.
3. `streetName` varchar
4. `streetTypeAbbrev` varchar abbreviated version of street type: e.g. St, Ave, Cir. These are controlled using the `street_type_lookup` table.
5. `postdirAbbrev` varchar abbreviated directional suffix of road N, S, E, W etc. These are controlled using the `direction_lookup` table.
6. `internal` varchar internal address such as an apartment or suite number.
7. `location` varchar usually a city or governing province.
8. `stateAbbrev` varchar two character US State. e.g MA, NY, MI. These are controlled by the `state_lookup` table.
9. `zip` varchar 5-digit zipcode. e.g. 02109.
10. `parsed` boolean - denotes if address was formed from normalize process. The `normalize_address` function sets this to true before returning the address.

## Examples

Output select fields. Use `Pprint_Addy` if you want a pretty textual output.

```
SELECT address As orig, (g.na).streetname, (g.na).streetypeabbrev
FROM (SELECT address, normalize_address(address) As na
 FROM addresses_to_geocode) As g;
```

orig	streetname	streetypeabbrev
28 Capen Street, Medford, MA	Capen	St
124 Mount Auburn St, Cambridge, Massachusetts 02138	Mount Auburn	St
950 Main Street, Worcester, MA 01610	Main	St
529 Main Street, Boston MA, 02129	Main	St
77 Massachusetts Avenue, Cambridge, MA 02139	Massachusetts	Ave
25 Wizard of Oz, Walford, KS 99912323	Wizard of Oz	

## See Also

### 13.1.14 Page\_Normalize\_Address

`Page_Normalize_Address` — Given a textual street address, returns a composite `norm_addy` type that has road suffix, prefix and type standardized, street, streetname etc. broken into separate fields. This function will work with just the lookup data packaged with the `tiger_geocoder` (no need for `tiger` census data). Requires `address_standardizer` extension.

## Synopsis

```
norm_addy page_normalize_address(varchar in_address);
```

## Description

Given a textual street address, returns a composite `norm_addy` type that has road suffix, prefix and type standardized, street, streetname etc. broken into separate fields. This is the first step in the geocoding process to get all addresses into normalized postal form. No other data is required aside from what is packaged with the geocoder.

This function just uses the various `page_*` lookup tables preloaded with the `tiger_geocoder` and located in the `tiger` schema, so it doesn't need you to download tiger census data or any other additional data to make use of it. You may find the need to add more abbreviations or alternative namings to the various lookup tables in the `tiger` schema.

It uses various control lookup tables located in `tiger` schema to normalize the input address.

Fields in the `norm_addy` type object returned by this function in this order where () indicates a field required by the geocoder, [] indicates an optional field:

There are slight variations in casing and formatting over the [Normalize\\_Address](#).

Availability: 2.1.0

This method needs `address_standardizer` extension.

```
(address) [predirAbbrev] (streetName) [streetTypeAbbrev] [postdirAbbrev] [internal] [location] [stateAbbrev] [zip]
```

The native `standardaddr` of `address_standardizer` extension is at this time a bit richer than `norm_addy` since its designed to support international addresses (including country). `standardaddr` equivalent fields are:

`house_num`, `predir`, `name`, `suftype`, `sufdir`, `unit`, `city`, `state`, `postcode`

1. `address` is an integer: The street number
2. `predirAbbrev` is varchar: Directional prefix of road such as N, S, E, W etc. These are controlled using the `direction_lookup` table.
3. `streetName` varchar
4. `streetTypeAbbrev` varchar abbreviated version of street type: e.g. St, Ave, Cir. These are controlled using the `street_type_lookup` table.
5. `postdirAbbrev` varchar abbreviated directional suffice of road N, S, E, W etc. These are controlled using the `direction_lookup` table.
6. `internal` varchar internal address such as an apartment or suite number.
7. `location` varchar usually a city or governing province.
8. `stateAbbrev` varchar two character US State. e.g MA, NY, MI. These are controlled by the `state_lookup` table.
9. `zip` varchar 5-digit zipcode. e.g. 02109.
10. `parsed` boolean - denotes if address was formed from normalize process. The `normalize_address` function sets this to true before returning the address.

## Examples

### Single call example

```
SELECT addy.*
FROM pagc_normalize_address('9000 E ROO ST STE 999, Springfield, CO') AS addy;
```

address	predirabbrev	streetname	streettypeabbrev	postdirabbrev	internal	location	stateabbrev	zip	parsed
9000	E	ROO	ST			SUITE 999	CO		t

Batch call. There are currently speed issues with the way `postgis_tiger_geocoder` wraps the `address_standardizer`. These will hopefully be resolved in later editions. To work around them, if you need speed for batch geocoding to call generate a normaddy in batch mode, you are encouraged to directly call the `address_standardizer` `standardize_address` function as shown below which is similar exercise to what we did in [Normalize\\_Address](#) that uses data created in [Geocode](#).

```
WITH g AS (SELECT address, ROW((sa).house_num, (sa).predir, (sa).name
, (sa).suftype, (sa).sufdir, (sa).unit , (sa).city, (sa).state, (sa).postcode, true)::
norm_addy As na
FROM (SELECT address, standardize_address('tiger.pagc_lex'
, 'tiger.pagc_gaz'
, 'tiger.pagc_rules', address) As sa
FROM addresses_to_geocode) As g)
SELECT address As orig, (g.na).streetname, (g.na).streettypeabbrev
FROM g;
```

orig	streetname	streettypeabbrev
529 Main Street, Boston MA, 02129	MAIN	ST
77 Massachusetts Avenue, Cambridge, MA 02139	MASSACHUSETTS	AVE
25 Wizard of Oz, Walaford, KS 99912323	WIZARD OF	
26 Capen Street, Medford, MA	CAPEN	ST
124 Mount Auburn St, Cambridge, Massachusetts 02138	MOUNT AUBURN	ST
950 Main Street, Worcester, MA 01610	MAIN	ST

### 13.1.15 Pprint\_Addy

`Pprint_Addy` — Given a `norm_addy` composite type object, returns a pretty print representation of it. Usually used in conjunction with `normalize_address`.

#### Synopsis

```
varchar pprint_addy(norm_addy in_addy);
```

#### Description

Given a `norm_addy` composite type object, returns a pretty print representation of it. No other data is required aside from what is packaged with the geocoder.

Usually used in conjunction with [Normalize\\_Address](#).

## Examples

### Pretty print a single address

```
SELECT pprint_addy(normalize_address('202 East Fremont Street, Las Vegas, Nevada 89101')) ←
 As pretty_address;
 pretty_address

202 E Fremont St, Las Vegas, NV 89101
```

### Pretty print address a table of addresses

```
SELECT address As orig, pprint_addy(normalize_address(address)) As pretty_address
 FROM addresses_to_geocode;
```

orig	pretty_address
529 Main Street, Boston MA, 02129	529 Main St, Boston MA, 02129
77 Massachusetts Avenue, Cambridge, MA 02139	77 Massachusetts Ave, Cambridge, MA ←
28 Capen Street, Medford, MA	28 Capen St, Medford, MA
124 Mount Auburn St, Cambridge, Massachusetts 02138	124 Mount Auburn St, Cambridge, MA ←
950 Main Street, Worcester, MA 01610	950 Main St, Worcester, MA 01610

## See Also

[Normalize\\_Address](#)

### 13.1.16 Reverse\_Geocode

**Reverse\_Geocode** — Takes a geometry point in a known spatial ref sys and returns a record containing an array of theoretically possible addresses and an array of cross streets. If `include_strnum_range = true`, includes the street range in the cross streets.

#### Synopsis

```
record Reverse_Geocode(geometry pt, boolean include_strnum_range=false, geometry[] OUT intpt, norm_addy[] OUT addy,
varchar[] OUT street);
```

#### Description

Takes a geometry point in a known spatial ref and returns a record containing an array of theoretically possible addresses and an array of cross streets. If `include_strnum_range = true`, includes the street range in the cross streets. `include_strnum_range` defaults to false if not passed in. Addresses are sorted according to which road a point is closest to so first address is most likely the right one.

Why do we say theoretical instead of actual addresses. The Tiger data doesn't have real addresses, but just street ranges. As such the theoretical address is an interpolated address based on the street ranges. Like for example interpolating one of my addresses returns a 26 Court St. and 26 Court Sq., though there is no such place as 26 Court Sq. This is because a point may be at a corner of 2 streets and thus the logic interpolates along both streets. The logic also assumes addresses are equally spaced along a street, which of course is wrong since you can have a municipal building taking up a good chunk of the street range and the rest of the buildings are clustered at the end.

Note: Hmm this function relies on Tiger data. If you have not loaded data covering the region of this point, then hmm you will get a record filled with NULLS.

Returned elements of the record are as follows:

1. `intpt` is an array of points: These are the center line points on the street closest to the input point. There are as many points as there are addresses.
2. `addy` is an array of `norm_addy` (normalized addresses): These are an array of possible addresses that fit the input point. The first one in the array is most likely. Generally there should be only one, except in the case when a point is at the corner of 2 or 3 streets, or the point is somewhere on the road and not off to the side.
3. `street` an array of `varchar`: These are cross streets (or the street) (streets that intersect or are the street the point is projected to be on).

Availability: 2.0.0

### Examples

Example of a point at the corner of two streets, but closest to one. This is approximate location of MIT: 77 Massachusetts Ave, Cambridge, MA 02139 Note that although we don't have 3 streets, PostgreSQL will just return null for entries above our upper bound so safe to use. This includes street ranges

```
SELECT pprint_addy(r.addy[1]) As st1, pprint_addy(r.addy[2]) As st2, pprint_addy(r.addy[3]) ←
 As st3,
 array_to_string(r.street, ',') As cross_streets
FROM reverse_geocode(ST_GeomFromText('POINT(-71.093902 42.359446)',4269),true) As r ←
;
```

result	st1	st2	st3	cross_streets
	67 Massachusetts Ave, Cambridge, MA 02139			67 - 127 Massachusetts Ave, 32 - 88 ← Vassar St

Here we choose not to include the address ranges for the cross streets and picked a location really really close to a corner of 2 streets thus could be known by two different addresses.

```
SELECT pprint_addy(r.addy[1]) As st1, pprint_addy(r.addy[2]) As st2,
pprint_addy(r.addy[3]) As st3, array_to_string(r.street, ',') As cross_str
FROM reverse_geocode(ST_GeomFromText('POINT(-71.06941 42.34225)',4269)) As r;
```

result	st1	st2	st3	cross_str
	5 Bradford St, Boston, MA 02118	49 Waltham St, Boston, MA 02118		Waltham St

For this one we reuse our geocoded example from [Geocode](#) and we only want the primary address and at most 2 cross streets.

```
SELECT actual_addr, lon, lat, pprint_addy((rg).addy[1]) As int_addr1,
(rg).street[1] As cross1, (rg).street[2] As cross2
FROM (SELECT address As actual_addr, lon, lat,
reverse_geocode(ST_SetSRID(ST_Point(lon,lat),4326)) As rg
FROM addresses_to_geocode WHERE rating > -1) As foo;
```

actual_addr	int_addr1	lon	lat	←	←
cross2				cross1	
529 Main Street, Boston MA, 02129 Boston, MA 02129	Medford St	-71.07181	42.38359	527 Main St, ←	

```

77 Massachusetts Avenue, Cambridge, MA 02139 | -71.09428 | 42.35988 | 77 ←

**13.1.17 Topology\_Load\_Tiger**

`Topology_Load_Tiger` — Loads a defined region of tiger data into a PostGIS Topology and transforming the tiger data to spatial reference of the topology and snapping to the precision tolerance of the topology.

**Synopsis**

```
text Topology_Load_Tiger(varchar topo_name, varchar region_type, varchar region_id);
```

**Description**

Loads a defined region of tiger data into a PostGIS Topology. The faces, nodes and edges are transformed to the spatial reference system of the target topology and points are snapped to the tolerance of the target topology. The created faces, nodes, edges maintain the same ids as the original Tiger data faces, nodes, edges so that datasets can be in the future be more easily reconciled with tiger data. Returns summary details about the process.

This would be useful for example for redistricting data where you require the newly formed polygons to follow the center lines of streets and for the resulting polygons not to overlap.

**Note**

This function relies on Tiger data as well as the installation of the PostGIS topology module. For more information, refer to Chapter 11 and Section 2.4.1. If you have not loaded data covering the region of interest, then no topology records will be created. This function will also fail if you have not created a topology using the topology functions.

**Note**

Most topology validation errors are a result of tolerance issues where after transformation the edges points don't quite line up or overlap. To remedy the situation you may want to increase or lower the precision if you get topology validation failures.

**Required arguments:**

1. `topo_name` The name of an existing PostGIS topology to load data into.
2. `region_type` The type of bounding region. Currently only `place` and `county` are supported. Plan is to have several more. This is the table to look into to define the region bounds. e.g `tiger.place`, `tiger.county`
3. `region_id` This is what TIGER calls the geoid. It is the unique identifier of the region in the table. For place it is the `plcidfp` column in `tiger.place`. For county it is the `cntyidfp` column in `tiger.county`

Availability: 2.0.0

**Example: Boston, Massachusetts Topology**

Create a topology for Boston, Massachusetts in Mass State Plane Feet (2249) with tolerance 0.25 feet and then load in Boston city tiger faces, edges, nodes.

```
SELECT topology.CreateTopology('topo_boston', 2249, 0.25);
createtopology

 15
-- 60,902 ms ~ 1 minute on windows 7 desktop running 9.1 (with 5 states tiger data loaded)

**13.1.18 Set\_Geocode\_Setting**

`Set_Geocode_Setting` — Sets a setting that affects behavior of geocoder functions.

**Synopsis**

```
text Set_Geocode_Setting(text setting_name, text setting_value);
```

**Description**

Sets value of specific setting stored in `tiger.geocode_settings` table. Settings allow you to toggle debugging of functions. Later plans will be to control rating with settings. Current list of settings are listed in [Get\\_Geocode\\_Setting](#).

Availability: 2.1.0

**Example return debugging setting**

If you run [Geocode](#) when this function is true, the NOTICE log will output timing and queries.

```
SELECT set_geocode_setting('debug_geocode_address', 'true') As result;
result

true
```

## Chapter 14

# PostGIS Special Functions Index

### 14.1 PostGIS Aggregate Functions

The functions given below are spatial aggregate functions provided with PostGIS that can be used just like any other sql aggregate function such as sum, average.

- **ST\_3DExtent** - an aggregate function that returns the box3D bounding box that bounds rows of geometries.
- **ST\_Accum** - Aggregate. Constructs an array of geometries.
- **ST\_ClusterIntersecting** - Aggregate. Returns an array with the connected components of a set of geometries
- **ST\_ClusterWithin** - Aggregate. Returns an array of GeometryCollections, where each GeometryCollection represents a set of geometries separated by no more than the specified distance.
- **ST\_Collect** - Return a specified ST\_Geometry value from a collection of other geometries.
- **ST\_Extent** - an aggregate function that returns the bounding box that bounds rows of geometries.
- **ST\_MakeLine** - Creates a Linestring from point, multipoint, or line geometries.
- **ST\_MemUnion** - Same as ST\_Union, only memory-friendly (uses less memory and more processor time).
- **ST\_Polygonize** - Aggregate. Creates a GeometryCollection containing possible polygons formed from the constituent linework of a set of geometries.
- **ST\_SameAlignment** - Returns true if rasters have same skew, scale, spatial ref, and offset (pixels can be put on same grid without cutting into pixels) and false if they don't with notice detailing issue.
- **ST\_Union** - Returns a geometry that represents the point set union of the Geometries.
- **TopoElementArray\_Agg** - Returns a topoelementarray for a set of element\_id, type arrays (topoelements)

### 14.2 PostGIS Window Functions

The functions given below are spatial window functions provided with PostGIS that can be used just like any other sql window function such as row\_number(), lead(), lag(). All these require an SQL OVER() clause.

- **ST\_ClusterDBSCAN** - Windowing function that returns integer id for the cluster each input geometry is in based on 2D implementation of Density-based spatial clustering of applications with noise (DBSCAN) algorithm.
  - **ST\_ClusterKMeans** - Windowing function that returns integer id for the cluster each input geometry is in.
-

## 14.3 PostGIS SQL-MM Compliant Functions

The functions given below are PostGIS functions that conform to the SQL/MM 3 standard

### Note

SQL-MM defines the default SRID of all geometry constructors as 0. PostGIS uses a default SRID of -1.

- **ST\_3DDWithin** - For 3d (z) geometry type Returns true if two geometries 3d distance is within number of units. This method implements the SQL/MM specification. SQL-MM ?
- **ST\_3DDistance** - For geometry type Returns the 3-dimensional cartesian minimum distance (based on spatial ref) between two geometries in projected units. This method implements the SQL/MM specification. SQL-MM ?
- **ST\_3DIntersects** - Returns TRUE if the Geometries "spatially intersect" in 3d - only for points, linestrings, polygons, polyhedral surface (area). With SFCGAL backend enabled also supports TINS This method implements the SQL/MM specification. SQL-MM 3: ?
- **ST\_AddEdgeModFace** - Add a new edge and, if in doing so it splits a face, modify the original face and add a new face. This method implements the SQL/MM specification. SQL-MM: Topo-Geo and Topo-Net 3: Routine Details: X.3.13
- **ST\_AddEdgeNewFaces** - Add a new edge and, if in doing so it splits a face, delete the original face and replace it with two new faces. This method implements the SQL/MM specification. SQL-MM: Topo-Geo and Topo-Net 3: Routine Details: X.3.12
- **ST\_AddIsoEdge** - Adds an isolated edge defined by geometry alinestring to a topology connecting two existing isolated nodes anode and another node and returns the edge id of the new edge. This method implements the SQL/MM specification. SQL-MM: Topo-Geo and Topo-Net 3: Routine Details: X.3.4
- **ST\_AddIsoNode** - Adds an isolated node to a face in a topology and returns the nodeid of the new node. If face is null, the node is still created. This method implements the SQL/MM specification. SQL-MM: Topo-Net Routines: X+1.3.1
- **ST\_Area** - Returns the area of the surface if it is a Polygon or MultiPolygon. For geometry, a 2D Cartesian area is determined with units specified by the SRID. For geography, area is determined on a curved surface with units in square meters. This method implements the SQL/MM specification. SQL-MM 3: 8.1.2, 9.5.3
- **ST\_AsBinary** - Return the Well-Known Binary (WKB) representation of the geometry/geography without SRID meta data. This method implements the SQL/MM specification. SQL-MM 3: 5.1.37
- **ST\_AsText** - Return the Well-Known Text (WKT) representation of the geometry/geography without SRID metadata. This method implements the SQL/MM specification. SQL-MM 3: 5.1.25
- **ST\_Boundary** - Returns the closure of the combinatorial boundary of this Geometry. This method implements the SQL/MM specification. SQL-MM 3: 5.1.14
- **ST\_Buffer** - (T)Returns a geometry covering all points within a given distance from the input geometry. This method implements the SQL/MM specification. SQL-MM 3: 5.1.17
- **ST\_Centroid** - Returns the geometric center of a geometry. This method implements the SQL/MM specification. SQL-MM 3: 8.1.4, 9.5.5
- **ST\_ChangeEdgeGeom** - Changes the shape of an edge without affecting the topology structure. This method implements the SQL/MM specification. SQL-MM: Topo-Geo and Topo-Net 3: Routine Details X.3.6
- **ST\_Contains** - Returns true if and only if no points of B lie in the exterior of A, and at least one point of the interior of B lies in the interior of A. This method implements the SQL/MM specification. SQL-MM 3: 5.1.31
- **ST\_ConvexHull** - The convex hull of a geometry represents the minimum convex geometry that encloses all geometries within the set. This method implements the SQL/MM specification. SQL-MM 3: 5.1.16

- **ST\_CoordDim** - Return the coordinate dimension of the ST\_Geometry value. This method implements the SQL/MM specification. SQL-MM 3: 5.1.3
  - **ST\_CreateTopoGeo** - Adds a collection of geometries to a given empty topology and returns a message detailing success. This method implements the SQL/MM specification. SQL-MM: Topo-Geo and Topo-Net 3: Routine Details -- X.3.18
  - **ST\_Crosses** - Returns TRUE if the supplied geometries have some, but not all, interior points in common. This method implements the SQL/MM specification. SQL-MM 3: 5.1.29
  - **ST\_CurveToLine** - Converts a CIRCULARSTRING/CURVEPOLYGON to a LINestring/POLYGON This method implements the SQL/MM specification. SQL-MM 3: 7.1.7
  - **ST\_Difference** - Returns a geometry that represents that part of geometry A that does not intersect with geometry B. This method implements the SQL/MM specification. SQL-MM 3: 5.1.20
  - **ST\_Dimension** - The inherent dimension of this Geometry object, which must be less than or equal to the coordinate dimension. This method implements the SQL/MM specification. SQL-MM 3: 5.1.2
  - **ST\_Disjoint** - Returns TRUE if the Geometries do not "spatially intersect" - if they do not share any space together. This method implements the SQL/MM specification. SQL-MM 3: 5.1.26
  - **ST\_Distance** - For geometry type Returns the 2D Cartesian distance between two geometries in projected units (based on spatial ref). For geography type defaults to return minimum geodesic distance between two geographies in meters. This method implements the SQL/MM specification. SQL-MM 3: 5.1.23
  - **ST\_EndPoint** - Returns the last point of a LINestring or CIRCULARLINestring geometry as a POINT. This method implements the SQL/MM specification. SQL-MM 3: 7.1.4
  - **ST\_Envelope** - Returns a geometry representing the double precision (float8) bounding box of the supplied geometry. This method implements the SQL/MM specification. SQL-MM 3: 5.1.15
  - **ST\_Equals** - Returns true if the given geometries represent the same geometry. Directionality is ignored. This method implements the SQL/MM specification. SQL-MM 3: 5.1.24
  - **ST\_ExteriorRing** - Returns a line string representing the exterior ring of the POLYGON geometry. Return NULL if the geometry is not a polygon. Will not work with MULTIPOLYGON This method implements the SQL/MM specification. SQL-MM 3: 8.2.3, 8.3.3
  - **ST\_GMLToSQL** - Return a specified ST\_Geometry value from GML representation. This is an alias name for ST\_GeomFromGML This method implements the SQL/MM specification. SQL-MM 3: 5.1.50 (except for curves support).
  - **ST\_GeomCollFromText** - Makes a collection Geometry from collection WKT with the given SRID. If SRID is not give, it defaults to 0. This method implements the SQL/MM specification.
  - **ST\_GeomFromText** - Return a specified ST\_Geometry value from Well-Known Text representation (WKT). This method implements the SQL/MM specification. SQL-MM 3: 5.1.40
  - **ST\_GeomFromWKB** - Creates a geometry instance from a Well-Known Binary geometry representation (WKB) and optional SRID. This method implements the SQL/MM specification. SQL-MM 3: 5.1.41
  - **ST\_GeometryFromText** - Return a specified ST\_Geometry value from Well-Known Text representation (WKT). This is an alias name for ST\_GeomFromText This method implements the SQL/MM specification. SQL-MM 3: 5.1.40
  - **ST\_GeometryN** - Return the 1-based Nth geometry if the geometry is a GEOMETRYCOLLECTION, (MULTI)POINT, (MULTI)LINestring, MULTICURVE or (MULTI)POLYGON, POLYHEDRALSURFACE Otherwise, return NULL. This method implements the SQL/MM specification. SQL-MM 3: 9.1.5
  - **ST\_GeometryType** - Return the geometry type of the ST\_Geometry value. This method implements the SQL/MM specification. SQL-MM 3: 5.1.4
  - **ST\_GetFaceEdges** - Returns a set of ordered edges that bound a face. This method implements the SQL/MM specification. SQL-MM 3 Topo-Geo and Topo-Net 3: Routine Details: X.3.5
-

- **ST\_GetFaceGeometry** - Returns the polygon in the given topology with the specified face id. This method implements the SQL/MM specification. SQL-MM 3 Topo-Geo and Topo-Net 3: Routine Details: X.3.16
  - **ST\_InitTopoGeo** - Creates a new topology schema and registers this new schema in the topology.topology table and details summary of process. This method implements the SQL/MM specification. SQL-MM 3 Topo-Geo and Topo-Net 3: Routine Details: X.3.17
  - **ST\_InteriorRingN** - Return the Nth interior linestring ring of the polygon geometry. Return NULL if the geometry is not a polygon or the given N is out of range. This method implements the SQL/MM specification. SQL-MM 3: 8.2.6, 8.3.5
  - **ST\_Intersection** - (T)Returns a geometry that represents the shared portion of geomA and geomB. This method implements the SQL/MM specification. SQL-MM 3: 5.1.18
  - **ST\_Intersects** - Returns TRUE if the Geometries/Geography "spatially intersect in 2D" - (share any portion of space) and FALSE if they don't (they are Disjoint). For geography -- tolerance is 0.00001 meters (so any points that close are considered to intersect) This method implements the SQL/MM specification. SQL-MM 3: 5.1.27
  - **ST\_IsClosed** - Returns TRUE if the LINESTRING's start and end points are coincident. For Polyhedral surface is closed (volumetric). This method implements the SQL/MM specification. SQL-MM 3: 7.1.5, 9.3.3
  - **ST\_IsEmpty** - Returns true if this Geometry is an empty geometrycollection, polygon, point etc. This method implements the SQL/MM specification. SQL-MM 3: 5.1.7
  - **ST\_IsRing** - Returns TRUE if this LINESTRING is both closed and simple. This method implements the SQL/MM specification. SQL-MM 3: 7.1.6
  - **ST\_IsSimple** - Returns (TRUE) if this Geometry has no anomalous geometric points, such as self intersection or self tangency. This method implements the SQL/MM specification. SQL-MM 3: 5.1.8
  - **ST\_IsValid** - Returns true if the ST\_Geometry is well formed. This method implements the SQL/MM specification. SQL-MM 3: 5.1.9
  - **ST\_Length** - Returns the 2D length of the geometry if it is a LineString or MultiLineString. geometry are in units of spatial reference and geography are in meters (default spheroid) This method implements the SQL/MM specification. SQL-MM 3: 7.1.2, 9.3.4
  - **ST\_LineFromText** - Makes a Geometry from WKT representation with the given SRID. If SRID is not given, it defaults to 0. This method implements the SQL/MM specification. SQL-MM 3: 7.2.8
  - **ST\_LineFromWKB** - Makes a LINESTRING from WKB with the given SRID This method implements the SQL/MM specification. SQL-MM 3: 7.2.9
  - **ST\_LinestringFromWKB** - Makes a geometry from WKB with the given SRID. This method implements the SQL/MM specification. SQL-MM 3: 7.2.9
  - **ST\_M** - Return the M coordinate of the point, or NULL if not available. Input must be a point. This method implements the SQL/MM specification.
  - **ST\_MLineFromText** - Return a specified ST\_MultiLineString value from WKT representation. This method implements the SQL/MM specification. SQL-MM 3: 9.4.4
  - **ST\_MPointFromText** - Makes a Geometry from WKT with the given SRID. If SRID is not give, it defaults to 0. This method implements the SQL/MM specification. SQL-MM 3: 9.2.4
  - **ST\_MPolyFromText** - Makes a MultiPolygon Geometry from WKT with the given SRID. If SRID is not give, it defaults to 0. This method implements the SQL/MM specification. SQL-MM 3: 9.6.4
  - **ST\_ModEdgeHeal** - Heal two edges by deleting the node connecting them, modifying the first edge and deleting the second edge. Returns the id of the deleted node. This method implements the SQL/MM specification. SQL-MM: Topo-Geo and Topo-Net 3: Routine Details: X.3.9
  - **ST\_ModEdgeSplit** - Split an edge by creating a new node along an existing edge, modifying the original edge and adding a new edge. This method implements the SQL/MM specification. SQL-MM: Topo-Geo and Topo-Net 3: Routine Details: X.3.9
-

- **ST\_MoveIsoNode** - Moves an isolated node in a topology from one point to another. If new apoint geometry exists as a node an error is thrown. RReturns description of move. This method implements the SQL/MM specification. SQL-MM: Topo-Net Routines: X.3.2
  - **ST\_NewEdgeHeal** - Heal two edges by deleting the node connecting them, deleting both edges, and replacing them with an edge whose direction is the same as the first edge provided. This method implements the SQL/MM specification. SQL-MM: Topo-Geo and Topo-Net 3: Routine Details: X.3.9
  - **ST\_NewEdgesSplit** - Split an edge by creating a new node along an existing edge, deleting the original edge and replacing it with two new edges. Returns the id of the new node created that joins the new edges. This method implements the SQL/MM specification. SQL-MM: Topo-Net Routines: X.3.8
  - **ST\_NumGeometries** - If geometry is a GEOMETRYCOLLECTION (or MULTI\*) return the number of geometries, for single geometries will return 1, otherwise return NULL. This method implements the SQL/MM specification. SQL-MM 3: 9.1.4
  - **ST\_NumInteriorRings** - Return the number of interior rings of a polygon geometry. This method implements the SQL/MM specification. SQL-MM 3: 8.2.5
  - **ST\_NumPatches** - Return the number of faces on a Polyhedral Surface. Will return null for non-polyhedral geometries. This method implements the SQL/MM specification. SQL-MM 3: ?
  - **ST\_NumPoints** - Return the number of points in an ST\_LineString or ST\_CircularString value. This method implements the SQL/MM specification. SQL-MM 3: 7.2.4
  - **ST\_OrderingEquals** - Returns true if the given geometries represent the same geometry and points are in the same directional order. This method implements the SQL/MM specification. SQL-MM 3: 5.1.43
  - **ST\_Overlaps** - Returns TRUE if the Geometries share space, are of the same dimension, but are not completely contained by each other. This method implements the SQL/MM specification. SQL-MM 3: 5.1.32
  - **ST\_PatchN** - Return the 1-based Nth geometry (face) if the geometry is a POLYHEDRALSURFACE, POLYHEDRALSURFACEM. Otherwise, return NULL. This method implements the SQL/MM specification. SQL-MM 3: ?
  - **ST\_Perimeter** - Return the length measurement of the boundary of an ST\_Surface or ST\_MultiSurface geometry or geography. (Polygon, MultiPolygon). geometry measurement is in units of spatial reference and geography is in meters. This method implements the SQL/MM specification. SQL-MM 3: 8.1.3, 9.5.4
  - **ST\_Point** - Returns an ST\_Point with the given coordinate values. OGC alias for ST\_MakePoint. This method implements the SQL/MM specification. SQL-MM 3: 6.1.2
  - **ST\_PointFromText** - Makes a point Geometry from WKT with the given SRID. If SRID is not given, it defaults to unknown. This method implements the SQL/MM specification. SQL-MM 3: 6.1.8
  - **ST\_PointFromWKB** - Makes a geometry from WKB with the given SRID This method implements the SQL/MM specification. SQL-MM 3: 6.1.9
  - **ST\_PointN** - Return the Nth point in the first LineString or circular LineString in the geometry. Negative values are counted backwards from the end of the LineString. Returns NULL if there is no linestring in the geometry. This method implements the SQL/MM specification. SQL-MM 3: 7.2.5, 7.3.5
  - **ST\_PointOnSurface** - Returns a POINT guaranteed to lie on the surface. This method implements the SQL/MM specification. SQL-MM 3: 8.1.5, 9.5.6. According to the specs, ST\_PointOnSurface works for surface geometries (POLYGONS, MULTIPOLYGONS, CURVED POLYGONS). So PostGIS seems to be extending what the spec allows here. Most databases Oracle, DB II, ESRI SDE seem to only support this function for surfaces. SQL Server 2008 like PostGIS supports for all common geometries.
  - **ST\_Polygon** - Returns a polygon built from the specified linestring and SRID. This method implements the SQL/MM specification. SQL-MM 3: 8.3.2
  - **ST\_PolygonFromText** - Makes a Geometry from WKT with the given SRID. If SRID is not give, it defaults to 0. This method implements the SQL/MM specification. SQL-MM 3: 8.3.6
-

- **ST\_Relate** - Returns true if this Geometry is spatially related to another Geometry, by testing for intersections between the Interior, Boundary and Exterior of the two geometries as specified by the values in the intersectionMatrixPattern. If no intersectionMatrixPattern is passed in, then returns the maximum intersectionMatrixPattern that relates the 2 geometries. This method implements the SQL/MM specification. SQL-MM 3: 5.1.25
  - **ST\_RemEdgeModFace** - Removes an edge and, if the removed edge separated two faces, delete one of the them and modify the other to take the space of both. This method implements the SQL/MM specification. SQL-MM: Topo-Geo and Topo-Net 3: Routine Details: X.3.15
  - **ST\_RemEdgeNewFace** - Removes an edge and, if the removed edge separated two faces, delete the original faces and replace them with a new face. This method implements the SQL/MM specification. SQL-MM: Topo-Geo and Topo-Net 3: Routine Details: X.3.14
  - **ST\_RemoveIsoEdge** - Removes an isolated edge and returns description of action. If the edge is not isolated, then an exception is thrown. This method implements the SQL/MM specification. SQL-MM: Topo-Geo and Topo-Net 3: Routine Details: X+1.3.3
  - **ST\_RemoveIsoNode** - Removes an isolated node and returns description of action. If the node is not isolated (is start or end of an edge), then an exception is thrown. This method implements the SQL/MM specification. SQL-MM: Topo-Geo and Topo-Net 3: Routine Details: X+1.3.3
  - **ST\_SRID** - Returns the spatial reference identifier for the ST\_Geometry as defined in spatial\_ref\_sys table. This method implements the SQL/MM specification. SQL-MM 3: 5.1.5
  - **ST\_StartPoint** - Returns the first point of a LINESTRING geometry as a POINT. This method implements the SQL/MM specification. SQL-MM 3: 7.1.3
  - **ST\_SymDifference** - Returns a geometry that represents the portions of A and B that do not intersect. It is called a symmetric difference because  $ST\_SymDifference(A,B) = ST\_SymDifference(B,A)$ . This method implements the SQL/MM specification. SQL-MM 3: 5.1.21
  - **ST\_Touches** - Returns TRUE if the geometries have at least one point in common, but their interiors do not intersect. This method implements the SQL/MM specification. SQL-MM 3: 5.1.28
  - **ST\_Transform** - Return a new geometry with its coordinates transformed to a different spatial reference. This method implements the SQL/MM specification. SQL-MM 3: 5.1.6
  - **ST\_Union** - Returns a geometry that represents the point set union of the Geometries. This method implements the SQL/MM specification. SQL-MM 3: 5.1.19 the z-index (elevation) when polygons are involved.
  - **ST\_WKBToSQL** - Return a specified ST\_Geometry value from Well-Known Binary representation (WKB). This is an alias name for ST\_GeomFromWKB that takes no srid This method implements the SQL/MM specification. SQL-MM 3: 5.1.36
  - **ST\_WKTToSQL** - Return a specified ST\_Geometry value from Well-Known Text representation (WKT). This is an alias name for ST\_GeomFromText This method implements the SQL/MM specification. SQL-MM 3: 5.1.34
  - **ST\_Within** - Returns true if the geometry A is completely inside geometry B This method implements the SQL/MM specification. SQL-MM 3: 5.1.30
  - **ST\_X** - Return the X coordinate of the point, or NULL if not available. Input must be a point. This method implements the SQL/MM specification. SQL-MM 3: 6.1.3
  - **ST\_Y** - Return the Y coordinate of the point, or NULL if not available. Input must be a point. This method implements the SQL/MM specification. SQL-MM 3: 6.1.4
  - **ST\_Z** - Return the Z coordinate of the point, or NULL if not available. Input must be a point. This method implements the SQL/MM specification.
-

## 14.4 PostGIS Geography Support Functions

The functions and operators given below are PostGIS functions/operators that take as input or return as output a **geography** data type object.

### Note

Functions with a (T) are not native geodetic functions, and use a ST\_Transform call to and from geometry to do the operation. As a result, they may not behave as expected when going over dateline, poles, and for large geometries or geometry pairs that cover more than one UTM zone. Basic transform - (favoring UTM, Lambert Azimuthal (North/South), and falling back on mercator in worst case scenario)

- **ST\_Area** - Returns the area of the surface if it is a Polygon or MultiPolygon. For geometry, a 2D Cartesian area is determined with units specified by the SRID. For geography, area is determined on a curved surface with units in square meters.
- **ST\_AsBinary** - Return the Well-Known Binary (WKB) representation of the geometry/geography without SRID meta data.
- **ST\_AsEWKT** - Return the Well-Known Text (WKT) representation of the geometry with SRID meta data.
- **ST\_AsGML** - Return the geometry as a GML version 2 or 3 element.
- **ST\_AsGeoJSON** - Return the geometry as a GeoJSON element.
- **ST\_AsKML** - Return the geometry as a KML element. Several variants. Default version=2, default precision=15
- **ST\_AsSVG** - Returns a Geometry in SVG path data given a geometry or geography object.
- **ST\_AsText** - Return the Well-Known Text (WKT) representation of the geometry/geography without SRID metadata.
- **ST\_Azimuth** - Returns the north-based azimuth as the angle in radians measured clockwise from the vertical on pointA to pointB.
- **ST\_Buffer** - (T)Returns a geometry covering all points within a given distance from the input geometry.
- **ST\_CoveredBy** - Returns 1 (TRUE) if no point in Geometry/Geography A is outside Geometry/Geography B
- **ST\_Covers** - Returns 1 (TRUE) if no point in Geometry B is outside Geometry A
- **ST\_DWithin** - Returns true if the geometries are within the specified distance of one another. For geometry units are in those of spatial reference and For geography units are in meters and measurement is defaulted to use\_spheroid=true (measure around spheroid), for faster check, use\_spheroid=false to measure along sphere.
- **ST\_Distance** - For geometry type Returns the 2D Cartesian distance between two geometries in projected units (based on spatial ref). For geography type defaults to return minimum geodesic distance between two geographies in meters.
- **ST\_GeogFromText** - Return a specified geography value from Well-Known Text representation or extended (WKT).
- **ST\_GeogFromWKB** - Creates a geography instance from a Well-Known Binary geometry representation (WKB) or extended Well Known Binary (EWKB).
- **ST\_GeographyFromText** - Return a specified geography value from Well-Known Text representation or extended (WKT).
- **=** - Returns TRUE if A's bounding box is the same as B's. Uses double precision bounding box.
- **ST\_Intersection** - (T)Returns a geometry that represents the shared portion of geomA and geomB.
- **ST\_Intersects** - Returns TRUE if the Geometries/Geography "spatially intersect in 2D" - (share any portion of space) and FALSE if they don't (they are Disjoint). For geography -- tolerance is 0.00001 meters (so any points that close are considered to intersect)
- **ST\_Length** - Returns the 2D length of the geometry if it is a LineString or MultiLineString. geometry are in units of spatial reference and geography are in meters (default spheroid)

- **ST\_Perimeter** - Return the length measurement of the boundary of an ST\_Surface or ST\_MultiSurface geometry or geography. (Polygon, MultiPolygon). geometry measurement is in units of spatial reference and geography is in meters.
- **ST\_Project** - Returns a POINT projected from a start point using a distance in meters and bearing (azimuth) in radians.
- **ST\_Segmentize** - Return a modified geometry/geography having no segment longer than the given distance.
- **ST\_Summary** - Returns a text summary of the contents of the geometry.
- **<->** - Returns the 2D distance between A and B.
- **&&** - Returns TRUE if A's 2D bounding box intersects B's 2D bounding box.

## 14.5 PostGIS Raster Support Functions

The functions and operators given below are PostGIS functions/operators that take as input or return as output a **raster** data type object. Listed in alphabetical order.

- **Box3D** - Returns the box 3d representation of the enclosing box of the raster.
- **@** - Returns TRUE if A's bounding box is contained by B's. Uses double precision bounding box.
- **~** - Returns TRUE if A's bounding box is contains B's. Uses double precision bounding box.
- **=** - Returns TRUE if A's bounding box is the same as B's. Uses double precision bounding box.
- **&&** - Returns TRUE if A's bounding box intersects B's bounding box.
- **&<** - Returns TRUE if A's bounding box is to the left of B's.
- **&>** - Returns TRUE if A's bounding box is to the right of B's.
- **~=** - Returns TRUE if A's bounding box is the same as B's.
- **ST\_Retile** - Return a set of configured tiles from an arbitrarily tiled raster coverage.
- **ST\_AddBand** - Returns a raster with the new band(s) of given type added with given initial value in the given index location. If no index is specified, the band is added to the end.
- **ST\_AsBinary** - Return the Well-Known Binary (WKB) representation of the raster.
- **ST\_AsGDALRaster** - Return the raster tile in the designated GDAL Raster format. Raster formats are one of those supported by your compiled library. Use ST\_GDALRasters() to get a list of formats supported by your library.
- **ST\_AsJPEG** - Return the raster tile selected bands as a single Joint Photographic Exports Group (JPEG) image (byte array). If no band is specified and 1 or more than 3 bands, then only the first band is used. If only 3 bands then all 3 bands are used and mapped to RGB.
- **ST\_AsPNG** - Return the raster tile selected bands as a single portable network graphics (PNG) image (byte array). If 1, 3, or 4 bands in raster and no bands are specified, then all bands are used. If more 2 or more than 4 bands and no bands specified, then only band 1 is used. Bands are mapped to RGB or RGBA space.
- **ST\_AsRaster** - Converts a PostGIS geometry to a PostGIS raster.
- **ST\_AsTIFF** - Return the raster selected bands as a single TIFF image (byte array). If no band is specified, then will try to use all bands.
- **ST\_Aspect** - Returns the aspect (in degrees by default) of an elevation raster band. Useful for analyzing terrain.
- **ST\_Band** - Returns one or more bands of an existing raster as a new raster. Useful for building new rasters from existing rasters.
- **ST\_BandIsNoData** - Returns true if the band is filled with only nodata values.

- **ST\_BandMetaData** - Returns basic meta data for a specific raster band. band num 1 is assumed if none-specified.
  - **ST\_BandNoDataValue** - Returns the value in a given band that represents no data. If no band num 1 is assumed.
  - **ST\_BandPath** - Returns system file path to a band stored in file system. If no bandnum specified, 1 is assumed.
  - **ST\_BandPixelType** - Returns the type of pixel for given band. If no bandnum specified, 1 is assumed.
  - **ST\_Clip** - Returns the raster clipped by the input geometry. If band number not is specified, all bands are processed. If crop is not specified or TRUE, the output raster is cropped.
  - **ST\_ColorMap** - Creates a new raster of up to four 8BUI bands (grayscale, RGB, RGBA) from the source raster and a specified band. Band 1 is assumed if not specified.
  - **ST\_Contains** - Return true if no points of raster rastB lie in the exterior of raster rastA and at least one point of the interior of rastB lies in the interior of rastA.
  - **ST\_ContainsProperly** - Return true if rastB intersects the interior of rastA but not the boundary or exterior of rastA.
  - **ST\_ConvexHull** - Return the convex hull geometry of the raster including pixel values equal to BandNoDataValue. For regular shaped and non-skewed rasters, this gives the same result as ST\_Envelope so only useful for irregularly shaped or skewed rasters.
  - **ST\_Count** - Returns the number of pixels in a given band of a raster or raster coverage. If no band is specified defaults to band 1. If exclude\_nodata\_value is set to true, will only count pixels that are not equal to the nodata value.
  - **ST\_CountAgg** - Aggregate. Returns the number of pixels in a given band of a set of rasters. If no band is specified defaults to band 1. If exclude\_nodata\_value is set to true, will only count pixels that are not equal to the NODATA value.
  - **ST\_CoveredBy** - Return true if no points of raster rastA lie outside raster rastB.
  - **ST\_Covers** - Return true if no points of raster rastB lie outside raster rastA.
  - **ST\_DFullyWithin** - Return true if rasters rastA and rastB are fully within the specified distance of each other.
  - **ST\_DWithin** - Return true if rasters rastA and rastB are within the specified distance of each other.
  - **ST\_Disjoint** - Return true if raster rastA does not spatially intersect rastB.
  - **ST\_DumpAsPolygons** - Returns a set of geomval (geom,val) rows, from a given raster band. If no band number is specified, band num defaults to 1.
  - **ST\_DumpValues** - Get the values of the specified band as a 2-dimension array.
  - **ST\_Envelope** - Returns the polygon representation of the extent of the raster.
  - **ST\_FromGDALRaster** - Returns a raster from a supported GDAL raster file.
  - **ST\_GeoReference** - Returns the georeference meta data in GDAL or ESRI format as commonly seen in a world file. Default is GDAL.
  - **ST\_HasNoBand** - Returns true if there is no band with given band number. If no band number is specified, then band number 1 is assumed.
  - **ST\_Height** - Returns the height of the raster in pixels.
  - **ST\_HillShade** - Returns the hypothetical illumination of an elevation raster band using provided azimuth, altitude, brightness and scale inputs.
  - **ST\_Histogram** - Returns a set of record summarizing a raster or raster coverage data distribution separate bin ranges. Number of bins are autocomputed if not specified.
  - **ST\_Intersection** - Returns a raster or a set of geometry-pixelvalue pairs representing the shared portion of two rasters or the geometrical intersection of a vectorization of the raster and a geometry.
  - **ST\_Intersects** - Return true if raster rastA spatially intersects raster rastB.
-

- **ST\_IsEmpty** - Returns true if the raster is empty (width = 0 and height = 0). Otherwise, returns false.
  - **ST\_MakeEmptyRaster** - Returns an empty raster (having no bands) of given dimensions (width & height), upperleft X and Y, pixel size and rotation (scalex, scaley, skewx & skewy) and reference system (srid). If a raster is passed in, returns a new raster with the same size, alignment and SRID. If srid is left out, the spatial ref is set to unknown (0).
  - **ST\_MapAlgebra** - Callback function version - Returns a one-band raster given one or more input rasters, band indexes and one user-specified callback function.
  - **ST\_MapAlgebraExpr** - 1 raster band version: Creates a new one band raster formed by applying a valid PostgreSQL algebraic operation on the input raster band and of pixeltype provided. Band 1 is assumed if no band is specified.
  - **ST\_MapAlgebraExpr** - 2 raster band version: Creates a new one band raster formed by applying a valid PostgreSQL algebraic operation on the two input raster bands and of pixeltype provided. band 1 of each raster is assumed if no band numbers are specified. The resulting raster will be aligned (scale, skew and pixel corners) on the grid defined by the first raster and have its extent defined by the "extenttype" parameter. Values for "extenttype" can be: INTERSECTION, UNION, FIRST, SECOND.
  - **ST\_MapAlgebraFct** - 1 band version - Creates a new one band raster formed by applying a valid PostgreSQL function on the input raster band and of pixeltype provided. Band 1 is assumed if no band is specified.
  - **ST\_MapAlgebraFct** - 2 band version - Creates a new one band raster formed by applying a valid PostgreSQL function on the 2 input raster bands and of pixeltype provided. Band 1 is assumed if no band is specified. Extent type defaults to INTERSECTION if not specified.
  - **ST\_MapAlgebraFctNgb** - 1-band version: Map Algebra Nearest Neighbor using user-defined PostgreSQL function. Return a raster which values are the result of a PLPGSQL user function involving a neighborhood of values from the input raster band.
  - **ST\_MapAlgebra** - Expression version - Returns a one-band raster given one or two input rasters, band indexes and one or more user-specified SQL expressions.
  - **ST\_MemSize** - Returns the amount of space (in bytes) the raster takes.
  - **ST\_MetaData** - Returns basic meta data about a raster object such as pixel size, rotation (skew), upper, lower left, etc.
  - **ST\_MinConvexHull** - Return the convex hull geometry of the raster excluding NODATA pixels.
  - **ST\_NearestValue** - Returns the nearest non-NODATA value of a given band's pixel specified by a columnx and rowy or a geometric point expressed in the same spatial reference coordinate system as the raster.
  - **ST\_Neighborhood** - Returns a 2-D double precision array of the non-NODATA values around a given band's pixel specified by either a columnX and rowY or a geometric point expressed in the same spatial reference coordinate system as the raster.
  - **ST\_NotSameAlignmentReason** - Returns text stating if rasters are aligned and if not aligned, a reason why.
  - **ST\_NumBands** - Returns the number of bands in the raster object.
  - **ST\_Overlaps** - Return true if raster rastA and rastB intersect but one does not completely contain the other.
  - **ST\_PixelAsCentroid** - Returns the centroid (point geometry) of the area represented by a pixel.
  - **ST\_PixelAsCentroids** - Returns the centroid (point geometry) for each pixel of a raster band along with the value, the X and the Y raster coordinates of each pixel. The point geometry is the centroid of the area represented by a pixel.
  - **ST\_PixelAsPoint** - Returns a point geometry of the pixel's upper-left corner.
  - **ST\_PixelAsPoints** - Returns a point geometry for each pixel of a raster band along with the value, the X and the Y raster coordinates of each pixel. The coordinates of the point geometry are of the pixel's upper-left corner.
  - **ST\_PixelAsPolygon** - Returns the polygon geometry that bounds the pixel for a particular row and column.
  - **ST\_PixelAsPolygons** - Returns the polygon geometry that bounds every pixel of a raster band along with the value, the X and the Y raster coordinates of each pixel.
  - **ST\_PixelHeight** - Returns the pixel height in geometric units of the spatial reference system.
-

- **ST\_PixelOfValue** - Get the columnx, rowy coordinates of the pixel whose value equals the search value.
  - **ST\_PixelWidth** - Returns the pixel width in geometric units of the spatial reference system.
  - **ST\_Polygon** - Returns a multipolygon geometry formed by the union of pixels that have a pixel value that is not no data value. If no band number is specified, band num defaults to 1.
  - **ST\_Quantile** - Compute quantiles for a raster or raster table coverage in the context of the sample or population. Thus, a value could be examined to be at the raster's 25%, 50%, 75% percentile.
  - **ST\_RasterToWorldCoord** - Returns the raster's upper left corner as geometric X and Y (longitude and latitude) given a column and row. Column and row starts at 1.
  - **ST\_RasterToWorldCoordX** - Returns the geometric X coordinate upper left of a raster, column and row. Numbering of columns and rows starts at 1.
  - **ST\_RasterToWorldCoordY** - Returns the geometric Y coordinate upper left corner of a raster, column and row. Numbering of columns and rows starts at 1.
  - **ST\_Reclass** - Creates a new raster composed of band types reclassified from original. The nband is the band to be changed. If nband is not specified assumed to be 1. All other bands are returned unchanged. Use case: convert a 16BUI band to a 8BUI and so forth for simpler rendering as viewable formats.
  - **ST\_Resample** - Resample a raster using a specified resampling algorithm, new dimensions, an arbitrary grid corner and a set of raster georeferencing attributes defined or borrowed from another raster.
  - **ST\_Rescale** - Resample a raster by adjusting only its scale (or pixel size). New pixel values are computed using the NearestNeighbor (english or american spelling), Bilinear, Cubic, CubicSpline or Lanczos resampling algorithm. Default is NearestNeighbor.
  - **ST\_Resize** - Resize a raster to a new width/height
  - **ST\_Reskew** - Resample a raster by adjusting only its skew (or rotation parameters). New pixel values are computed using the NearestNeighbor (english or american spelling), Bilinear, Cubic, CubicSpline or Lanczos resampling algorithm. Default is NearestNeighbor.
  - **ST\_Rotation** - Returns the rotation of the raster in radian.
  - **ST\_Roughness** - Returns a raster with the calculated "roughness" of a DEM.
  - **ST\_SRID** - Returns the spatial reference identifier of the raster as defined in spatial\_ref\_sys table.
  - **ST\_SameAlignment** - Returns true if rasters have same skew, scale, spatial ref, and offset (pixels can be put on same grid without cutting into pixels) and false if they don't with notice detailing issue.
  - **ST\_ScaleX** - Returns the X component of the pixel width in units of coordinate reference system.
  - **ST\_ScaleY** - Returns the Y component of the pixel height in units of coordinate reference system.
  - **ST\_SetBandIsNoData** - Sets the isnodata flag of the band to TRUE.
  - **ST\_SetBandNoDataValue** - Sets the value for the given band that represents no data. Band 1 is assumed if no band is specified. To mark a band as having no nodata value, set the nodata value = NULL.
  - **ST\_SetGeoReference** - Set Georeference 6 georeference parameters in a single call. Numbers should be separated by white space. Accepts inputs in GDAL or ESRI format. Default is GDAL.
  - **ST\_SetRotation** - Set the rotation of the raster in radian.
  - **ST\_SetSRID** - Sets the SRID of a raster to a particular integer srid defined in the spatial\_ref\_sys table.
  - **ST\_SetScale** - Sets the X and Y size of pixels in units of coordinate reference system. Number units/pixel width/height.
  - **ST\_SetSkew** - Sets the georeference X and Y skew (or rotation parameter). If only one is passed in, sets X and Y to the same value.
-

- **ST\_SetUpperLeft** - Sets the value of the upper left corner of the pixel to projected X and Y coordinates.
  - **ST\_SetValue** - Returns modified raster resulting from setting the value of a given band in a given columnx, rowy pixel or the pixels that intersect a particular geometry. Band numbers start at 1 and assumed to be 1 if not specified.
  - **ST\_SetValues** - Returns modified raster resulting from setting the values of a given band.
  - **ST\_SkewX** - Returns the georeference X skew (or rotation parameter).
  - **ST\_SkewY** - Returns the georeference Y skew (or rotation parameter).
  - **ST\_Slope** - Returns the slope (in degrees by default) of an elevation raster band. Useful for analyzing terrain.
  - **ST\_SnapToGrid** - Resample a raster by snapping it to a grid. New pixel values are computed using the NearestNeighbor (english or american spelling), Bilinear, Cubic, CubicSpline or Lanczos resampling algorithm. Default is NearestNeighbor.
  - **ST\_Summary** - Returns a text summary of the contents of the raster.
  - **ST\_SummaryStats** - Returns summarystats consisting of count, sum, mean, stddev, min, max for a given raster band of a raster or raster coverage. Band 1 is assumed is no band is specified.
  - **ST\_SummaryStatsAgg** - Aggregate. Returns summarystats consisting of count, sum, mean, stddev, min, max for a given raster band of a set of raster. Band 1 is assumed is no band is specified.
  - **ST\_TPI** - Returns a raster with the calculated Topographic Position Index.
  - **ST\_TRI** - Returns a raster with the calculated Terrain Ruggedness Index.
  - **ST\_Tile** - Returns a set of rasters resulting from the split of the input raster based upon the desired dimensions of the output rasters.
  - **ST\_Touches** - Return true if raster rastA and rastB have at least one point in common but their interiors do not intersect.
  - **ST\_Transform** - Reprojects a raster in a known spatial reference system to another known spatial reference system using specified resampling algorithm. Options are NearestNeighbor, Bilinear, Cubic, CubicSpline, Lanczos defaulting to NearestNeighbor.
  - **ST\_Union** - Returns the union of a set of raster tiles into a single raster composed of 1 or more bands.
  - **ST\_UpperLeftX** - Returns the upper left X coordinate of raster in projected spatial ref.
  - **ST\_UpperLeftY** - Returns the upper left Y coordinate of raster in projected spatial ref.
  - **ST\_Value** - Returns the value of a given band in a given columnx, rowy pixel or at a particular geometric point. Band numbers start at 1 and assumed to be 1 if not specified. If exclude\_nodata\_value is set to false, then all pixels include nodata pixels are considered to intersect and return value. If exclude\_nodata\_value is not passed in then reads it from metadata of raster.
  - **ST\_ValueCount** - Returns a set of records containing a pixel band value and count of the number of pixels in a given band of a raster (or a raster coverage) that have a given set of values. If no band is specified defaults to band 1. By default nodata value pixels are not counted, and all other values in the pixel are output and pixel band values are rounded to the nearest integer.
  - **ST\_Width** - Returns the width of the raster in pixels.
  - **ST\_Within** - Return true if no points of raster rastA lie in the exterior of raster rastB and at least one point of the interior of rastA lies in the interior of rastB.
  - **ST\_WorldToRasterCoord** - Returns the upper left corner as column and row given geometric X and Y (longitude and latitude) or a point geometry expressed in the spatial reference coordinate system of the raster.
  - **ST\_WorldToRasterCoordX** - Returns the column in the raster of the point geometry (pt) or a X and Y world coordinate (xw, yw) represented in world spatial reference system of raster.
  - **ST\_WorldToRasterCoordY** - Returns the row in the raster of the point geometry (pt) or a X and Y world coordinate (xw, yw) represented in world spatial reference system of raster.
  - **UpdateRasterSRID** - Change the SRID of all rasters in the user-specified column and table.
-

## 14.6 PostGIS Geometry / Geography / Raster Dump Functions

The functions given below are PostGIS functions that take as input or return as output a set of or single `geometry_dump` or `geomval` data type object.

- **ST\_DumpAsPolygons** - Returns a set of `geomval` (`geom, val`) rows, from a given raster band. If no band number is specified, band num defaults to 1.
- **ST\_Intersection** - Returns a raster or a set of geometry-pixelvalue pairs representing the shared portion of two rasters or the geometrical intersection of a vectorization of the raster and a geometry.
- **ST\_Dump** - Returns a set of `geometry_dump` (`geom, path`) rows, that make up a geometry `g1`.
- **ST\_DumpPoints** - Returns a set of `geometry_dump` (`geom, path`) rows of all points that make up a geometry.
- **ST\_DumpRings** - Returns a set of `geometry_dump` rows, representing the exterior and interior rings of a polygon.

## 14.7 PostGIS Box Functions

The functions given below are PostGIS functions that take as input or return as output the `box*` family of PostGIS spatial types. The box family of types consists of `box2d`, and `box3d`

- **Box2D** - Returns a BOX2D representing the maximum extents of the geometry.
- **Box3D** - Returns a BOX3D representing the maximum extents of the geometry.
- **Box3D** - Returns the box 3d representation of the enclosing box of the raster.
- **ST\_3DExtent** - an aggregate function that returns the box3D bounding box that bounds rows of geometries.
- **ST\_3DMakeBox** - Creates a BOX3D defined by the given 3d point geometries.
- **ST\_AsTWKB** - Returns the geometry as TWKB, aka "Tiny Well-Known Binary"
- **ST\_Box2dFromGeoHash** - Return a BOX2D from a GeoHash string.
- **ST\_ClipByBox2D** - Returns the portion of a geometry falling within a rectangle.
- **ST\_EstimatedExtent** - Return the 'estimated' extent of the given spatial table. The estimated is taken from the geometry column's statistics. The current schema will be used if not specified.
- **ST\_Expand** - Returns bounding box expanded in all directions from the bounding box of the input geometry. Uses double-precision
- **ST\_Extent** - an aggregate function that returns the bounding box that bounds rows of geometries.
- **ST\_MakeBox2D** - Creates a BOX2D defined by the given point geometries.
- **ST\_XMax** - Returns X maxima of a bounding box 2d or 3d or a geometry.
- **ST\_XMin** - Returns X minima of a bounding box 2d or 3d or a geometry.
- **ST\_YMax** - Returns Y maxima of a bounding box 2d or 3d or a geometry.
- **ST\_YMin** - Returns Y minima of a bounding box 2d or 3d or a geometry.
- **ST\_ZMax** - Returns Z minima of a bounding box 2d or 3d or a geometry.
- **ST\_ZMin** - Returns Z minima of a bounding box 2d or 3d or a geometry.
- **~(box2df, box2df)** - Returns TRUE if a 2D float precision bounding box (BOX2DF) contains another 2D float precision bounding box (BOX2DF).

- `~(box2df,geometry)` - Returns TRUE if a 2D float precision bounding box (BOX2DF) contains a geometry's 2D bounding box.
- `~(geometry,box2df)` - Returns TRUE if a geometry's 2D bounding box contains a 2D float precision bounding box (BOX2DF).
- `@(box2df,box2df)` - Returns TRUE if a 2D float precision bounding box (BOX2DF) is contained into another 2D float precision bounding box.
- `@(box2df,geometry)` - Returns TRUE if a 2D float precision bounding box (BOX2DF) is contained into a geometry's 2D bounding box.
- `@(geometry,box2df)` - Returns TRUE if a geometry's 2D bounding box is contained into a 2D float precision bounding box (BOX2DF).
- `&&(box2df,box2df)` - Returns TRUE if two 2D float precision bounding boxes (BOX2DF) intersect each other.
- `&&(box2df,geometry)` - Returns TRUE if a 2D float precision bounding box (BOX2DF) intersects a geometry's (cached) 2D bounding box.
- `&&(geometry,box2df)` - Returns TRUE if a geometry's (cached) 2D bounding box intersects a 2D float precision bounding box (BOX2DF).

## 14.8 PostGIS Functions that support 3D

The functions given below are PostGIS functions that do not throw away the Z-Index.

- `AddGeometryColumn` - Adds a geometry column to an existing table of attributes. By default uses type modifier to define rather than constraints. Pass in false for use\_typed to get old check constraint based behavior
- `Box3D` - Returns a BOX3D representing the maximum extents of the geometry.
- `DropGeometryColumn` - Removes a geometry column from a spatial table.
- `GeometryType` - Returns the type of the geometry as a string. Eg: 'LINESTRING', 'POLYGON', 'MULTIPOINT', etc.
- `ST_3DArea` - Computes area of 3D surface geometries. Will return 0 for solids.
- `ST_3DClosestPoint` - Returns the 3-dimensional point on g1 that is closest to g2. This is the first point of the 3D shortest line.
- `ST_3DDFullyWithin` - Returns true if all of the 3D geometries are within the specified distance of one another.
- `ST_3DDWithin` - For 3d (z) geometry type Returns true if two geometries 3d distance is within number of units.
- `ST_3DDifference` - Perform 3D difference
- `ST_3DDistance` - For geometry type Returns the 3-dimensional cartesian minimum distance (based on spatial ref) between two geometries in projected units.
- `ST_3DExtent` - an aggregate function that returns the box3D bounding box that bounds rows of geometries.
- `ST_3DIntersection` - Perform 3D intersection
- `ST_3DIntersects` - Returns TRUE if the Geometries "spatially intersect" in 3d - only for points, linestrings, polygons, polyhedral surface (area). With SFCGAL backend enabled also supports TINS
- `ST_3DLength` - Returns the 3-dimensional or 2-dimensional length of the geometry if it is a linestring or multi-linestring.
- `ST_3DLongestLine` - Returns the 3-dimensional longest line between two geometries
- `ST_3DMakeBox` - Creates a BOX3D defined by the given 3d point geometries.
- `ST_3DMaxDistance` - For geometry type Returns the 3-dimensional cartesian maximum distance (based on spatial ref) between two geometries in projected units.
- `ST_3DPerimeter` - Returns the 3-dimensional perimeter of the geometry, if it is a polygon or multi-polygon.

- **ST\_3DShortestLine** - Returns the 3-dimensional shortest line between two geometries
  - **ST\_3DUnion** - Perform 3D union
  - **ST\_Accum** - Aggregate. Constructs an array of geometries.
  - **ST\_AddMeasure** - Return a derived geometry with measure elements linearly interpolated between the start and end points.
  - **ST\_AddPoint** - Add a point to a LineString.
  - **ST\_Affine** - Apply a 3d affine transformation to a geometry.
  - **ST\_ApproximateMedialAxis** - Compute the approximate medial axis of an areal geometry.
  - **ST\_AsBinary** - Return the Well-Known Binary (WKB) representation of the geometry/geography without SRID meta data.
  - **ST\_AsEWKB** - Return the Well-Known Binary (WKB) representation of the geometry with SRID meta data.
  - **ST\_AsEWKT** - Return the Well-Known Text (WKT) representation of the geometry with SRID meta data.
  - **ST\_AsGML** - Return the geometry as a GML version 2 or 3 element.
  - **ST\_AsGeoJSON** - Return the geometry as a GeoJSON element.
  - **ST\_AsHEXEWKB** - Returns a Geometry in HEXEWKB format (as text) using either little-endian (NDR) or big-endian (XDR) encoding.
  - **ST\_AsKML** - Return the geometry as a KML element. Several variants. Default version=2, default precision=15
  - **ST\_AsX3D** - Returns a Geometry in X3D xml node element format: ISO-IEC-19776-1.2-X3DEncodings-XML
  - **ST\_Boundary** - Returns the closure of the combinatorial boundary of this Geometry.
  - **ST\_BoundingDiagonal** - Returns the diagonal of the supplied geometry's bounding box.
  - **ST\_CPAWithin** - Returns true if the trajectories' closest points of approach are within the specified distance.
  - **ST\_ClosestPointOfApproach** - Returns the measure at which points interpolated along two lines are closest.
  - **ST\_Collect** - Return a specified ST\_Geometry value from a collection of other geometries.
  - **ST\_ConvexHull** - The convex hull of a geometry represents the minimum convex geometry that encloses all geometries within the set.
  - **ST\_CoordDim** - Return the coordinate dimension of the ST\_Geometry value.
  - **ST\_CurveToLine** - Converts a CIRCULARSTRING/CURVEPOLYGON to a LINestring/POLYGON
  - **ST\_DelaunayTriangles** - Return a Delaunay triangulation around the given input points.
  - **ST\_Difference** - Returns a geometry that represents that part of geometry A that does not intersect with geometry B.
  - **ST\_DistanceCPA** - Returns the distance between closest points of approach in two trajectories.
  - **ST\_Dump** - Returns a set of geometry\_dump (geom,path) rows, that make up a geometry g1.
  - **ST\_DumpPoints** - Returns a set of geometry\_dump (geom,path) rows of all points that make up a geometry.
  - **ST\_DumpRings** - Returns a set of geometry\_dump rows, representing the exterior and interior rings of a polygon.
  - **ST\_EndPoint** - Returns the last point of a LINestring or CIRCULARLINestring geometry as a POINT.
  - **ST\_ExteriorRing** - Returns a line string representing the exterior ring of the POLYGON geometry. Return NULL if the geometry is not a polygon. Will not work with MULTIPOLYGON
  - **ST\_Extrude** - Extrude a surface to a related volume
-

- **ST\_FlipCoordinates** - Returns a version of the given geometry with X and Y axis flipped. Useful for people who have built latitude/longitude features and need to fix them.
  - **ST\_Force2D** - Force the geometries into a "2-dimensional mode".
  - **ST\_ForceCurve** - Upcast a geometry into its curved type, if applicable.
  - **ST\_ForceLHR** - Force LHR orientation
  - **ST\_ForceRHR** - Force the orientation of the vertices in a polygon to follow the Right-Hand-Rule.
  - **ST\_ForceSFS** - Force the geometries to use SFS 1.1 geometry types only.
  - **ST\_Force\_3D** - Force the geometries into XYZ mode. This is an alias for ST\_Force3DZ.
  - **ST\_Force\_3DZ** - Force the geometries into XYZ mode.
  - **ST\_Force\_4D** - Force the geometries into XYZM mode.
  - **ST\_Force\_Collection** - Convert the geometry into a GEOMETRYCOLLECTION.
  - **ST\_GeomFromEWKB** - Return a specified ST\_Geometry value from Extended Well-Known Binary representation (EWKB).
  - **ST\_GeomFromEWKT** - Return a specified ST\_Geometry value from Extended Well-Known Text representation (EWKT).
  - **ST\_GeomFromGML** - Takes as input GML representation of geometry and outputs a PostGIS geometry object
  - **ST\_GeomFromGeoJSON** - Takes as input a geojson representation of a geometry and outputs a PostGIS geometry object
  - **ST\_GeomFromKML** - Takes as input KML representation of geometry and outputs a PostGIS geometry object
  - **ST\_GeometricMedian** - Returns the geometric median of a MultiPoint.
  - **ST\_GeometryN** - Return the 1-based Nth geometry if the geometry is a GEOMETRYCOLLECTION, (MULTI)POINT, (MULTI)LINEMULTICURVE or (MULTI)POLYGON, POLYHEDRALSURFACE Otherwise, return NULL.
  - **ST\_GeometryType** - Return the geometry type of the ST\_Geometry value.
  - **ST\_HasArc** - Returns true if a geometry or geometry collection contains a circular string
  - **ST\_InteriorRingN** - Return the Nth interior linestring ring of the polygon geometry. Return NULL if the geometry is not a polygon or the given N is out of range.
  - **ST\_InterpolatePoint** - Return the value of the measure dimension of a geometry at the point closed to the provided point.
  - **ST\_IsClosed** - Returns TRUE if the LINESTRING's start and end points are coincident. For Polyhedral surface is closed (volumetric).
  - **ST\_IsCollection** - Returns TRUE if the argument is a collection (MULTI\*, GEOMETRYCOLLECTION, ...)
  - **ST\_IsPlanar** - Check if a surface is or not planar
  - **ST\_IsSimple** - Returns (TRUE) if this Geometry has no anomalous geometric points, such as self intersection or self tangency.
  - **ST\_IsSolid** - Test if the geometry is a solid. No validity check is performed.
  - **ST\_IsValidTrajectory** - Returns true if the geometry is a valid trajectory.
  - **ST\_Length\_Spheroid** - Calculates the 2D or 3D length/perimeter of a geometry on an ellipsoid. This is useful if the coordinates of the geometry are in longitude/latitude and a length is desired without reprojection.
  - **ST\_LineFromMultiPoint** - Creates a LineString from a MultiPoint geometry.
  - **ST\_LineInterpolatePoint** - Returns a point interpolated along a line. Second argument is a float8 between 0 and 1 representing fraction of total length of linestring the point has to be located.
  - **ST\_LineSubstring** - Return a linestring being a substring of the input one starting and ending at the given fractions of total 2d length. Second and third arguments are float8 values between 0 and 1.
-

- **ST\_LineToCurve** - Converts a LINESTRING/POLYGON to a CIRCULARSTRING, CURVEPOLYGON
  - **ST\_LocateBetweenElevations** - Return a derived geometry (collection) value with elements that intersect the specified range of elevations inclusively. Only 3D, 4D LINESTRINGS and MULTILINESTRINGS are supported.
  - **ST\_M** - Return the M coordinate of the point, or NULL if not available. Input must be a point.
  - **ST\_MakeLine** - Creates a Linestring from point, multipoint, or line geometries.
  - **ST\_MakePoint** - Creates a 2D,3DZ or 4D point geometry.
  - **ST\_MakePolygon** - Creates a Polygon formed by the given shell. Input geometries must be closed LINESTRINGS.
  - **ST\_MakeSolid** - Cast the geometry into a solid. No check is performed. To obtain a valid solid, the input geometry must be a closed Polyhedral Surface or a closed TIN.
  - **ST\_MakeValid** - Attempts to make an invalid geometry valid without losing vertices.
  - **ST\_MemSize** - Returns the amount of space (in bytes) the geometry takes.
  - **ST\_MemUnion** - Same as ST\_Union, only memory-friendly (uses less memory and more processor time).
  - **ST\_NDims** - Returns coordinate dimension of the geometry as a small int. Values are: 2,3 or 4.
  - **ST\_NPoints** - Return the number of points (vertexes) in a geometry.
  - **ST\_NRings** - If the geometry is a polygon or multi-polygon returns the number of rings.
  - **ST\_Node** - Node a set of linestrings.
  - **ST\_NumGeometries** - If geometry is a GEOMETRYCOLLECTION (or MULTI\*) return the number of geometries, for single geometries will return 1, otherwise return NULL.
  - **ST\_NumPatches** - Return the number of faces on a Polyhedral Surface. Will return null for non-polyhedral geometries.
  - **ST\_Orientation** - Determine surface orientation
  - **ST\_PatchN** - Return the 1-based Nth geometry (face) if the geometry is a POLYHEDRALSURFACE, POLYHEDRALSURFACEM. Otherwise, return NULL.
  - **ST\_PointFromWKB** - Makes a geometry from WKB with the given SRID
  - **ST\_PointN** - Return the Nth point in the first LineString or circular LineString in the geometry. Negative values are counted backwards from the end of the LineString. Returns NULL if there is no linestring in the geometry.
  - **ST\_PointOnSurface** - Returns a POINT guaranteed to lie on the surface.
  - **ST\_Points** - Returns a MultiPoint containing all of the coordinates of a geometry.
  - **ST\_Polygon** - Returns a polygon built from the specified linestring and SRID.
  - **ST\_RemovePoint** - Remove point from a linestring.
  - **ST\_RemoveRepeatedPoints** - Returns a version of the given geometry with duplicated points removed.
  - **ST\_Rotate** - Rotate a geometry rotRadians counter-clockwise about an origin.
  - **ST\_RotateX** - Rotate a geometry rotRadians about the X axis.
  - **ST\_RotateY** - Rotate a geometry rotRadians about the Y axis.
  - **ST\_RotateZ** - Rotate a geometry rotRadians about the Z axis.
  - **ST\_Scale** - Scale a geometry by given factors.
  - **ST\_SetPoint** - Replace point of a linestring with a given point.
  - **ST\_Shift\_Longitude** - Toggle geometry coordinates between -180..180 and 0..360 ranges.
-

- **ST\_SnapToGrid** - Snap all points of the input geometry to a regular grid.
  - **ST\_StartPoint** - Returns the first point of a LINESTRING geometry as a POINT.
  - **ST\_StraightSkeleton** - Compute a straight skeleton from a geometry
  - **ST\_SwapOrdinates** - Returns a version of the given geometry with given ordinate values swapped.
  - **ST\_SymDifference** - Returns a geometry that represents the portions of A and B that do not intersect. It is called a symmetric difference because  $ST\_SymDifference(A,B) = ST\_SymDifference(B,A)$ .
  - **ST\_Tessellate** - Perform surface Tessellation of a polygon or polyhedralsurface and returns as a TIN or collection of TINS
  - **ST\_TransScale** - Translate a geometry by given factors and offsets.
  - **ST\_Translate** - Translate a geometry by given offsets.
  - **ST\_UnaryUnion** - Like ST\_Union, but working at the geometry component level.
  - **ST\_Volume** - Computes the volume of a 3D solid. If applied to surface (even closed) geometries will return 0.
  - **ST\_WrapX** - Wrap a geometry around an X value.
  - **ST\_X** - Return the X coordinate of the point, or NULL if not available. Input must be a point.
  - **ST\_XMax** - Returns X maxima of a bounding box 2d or 3d or a geometry.
  - **ST\_XMin** - Returns X minima of a bounding box 2d or 3d or a geometry.
  - **ST\_Y** - Return the Y coordinate of the point, or NULL if not available. Input must be a point.
  - **ST\_YMax** - Returns Y maxima of a bounding box 2d or 3d or a geometry.
  - **ST\_YMin** - Returns Y minima of a bounding box 2d or 3d or a geometry.
  - **ST\_Z** - Return the Z coordinate of the point, or NULL if not available. Input must be a point.
  - **ST\_ZMax** - Returns Z minima of a bounding box 2d or 3d or a geometry.
  - **ST\_ZMin** - Returns Z minima of a bounding box 2d or 3d or a geometry.
  - **ST\_Zmflag** - Returns ZM (dimension semantic) flag of the geometries as a small int. Values are: 0=2d, 1=3dm, 2=3dz, 3=4d.
  - **TG\_Equals** - Returns true if two topogeometries are composed of the same topology primitives.
  - **TG\_Intersects** - Returns true if any pair of primitives from the two topogeometries intersect.
  - **UpdateGeometrySRID** - Updates the SRID of all features in a geometry column, geometry\_columns metadata and srid. If it was enforced with constraints, the constraints will be updated with new srid constraint. If the old was enforced by type definition, the type definition will be changed.
  - **geometry\_overlaps\_nd** - Returns TRUE if A's n-D bounding box intersects B's n-D bounding box.
  - **overlaps\_nd\_geometry\_gidx** - Returns TRUE if a geometry's (cached) n-D bounding box intersects a n-D float precision bounding box (GIDX).
  - **overlaps\_nd\_gidx\_geometry** - Returns TRUE if a n-D float precision bounding box (GIDX) intersects a geometry's (cached) n-D bounding box.
  - **overlaps\_nd\_gidx\_gidx** - Returns TRUE if two n-D float precision bounding boxes (GIDX) intersect each other.
  - **postgis\_sfcgal\_version** - Returns the version of SFCGAL in use
-

## 14.9 PostGIS Curved Geometry Support Functions

The functions given below are PostGIS functions that can use CIRCULARSTRING, CURVEPOLYGON, and other curved geometry types

- **AddGeometryColumn** - Adds a geometry column to an existing table of attributes. By default uses type modifier to define rather than constraints. Pass in false for use\_typmod to get old check constraint based behavior
  - **Box2D** - Returns a BOX2D representing the maximum extents of the geometry.
  - **Box3D** - Returns a BOX3D representing the maximum extents of the geometry.
  - **DropGeometryColumn** - Removes a geometry column from a spatial table.
  - **GeometryType** - Returns the type of the geometry as a string. Eg: 'LINESTRING', 'POLYGON', 'MULTIPOINT', etc.
  - **PostGIS\_AddBBox** - Add bounding box to the geometry.
  - **PostGIS\_DropBBox** - Drop the bounding box cache from the geometry.
  - **PostGIS\_HasBBox** - Returns TRUE if the bbox of this geometry is cached, FALSE otherwise.
  - **ST\_3DExtent** - an aggregate function that returns the box3D bounding box that bounds rows of geometries.
  - **ST\_Accum** - Aggregate. Constructs an array of geometries.
  - **ST\_Affine** - Apply a 3d affine transformation to a geometry.
  - **ST\_AsBinary** - Return the Well-Known Binary (WKB) representation of the geometry/geography without SRID meta data.
  - **ST\_AsEWKB** - Return the Well-Known Binary (WKB) representation of the geometry with SRID meta data.
  - **ST\_AsEWKT** - Return the Well-Known Text (WKT) representation of the geometry with SRID meta data.
  - **ST\_AsHEXEWKB** - Returns a Geometry in HEXEWKB format (as text) using either little-endian (NDR) or big-endian (XDR) encoding.
  - **ST\_AsText** - Return the Well-Known Text (WKT) representation of the geometry/geography without SRID metadata.
  - **ST\_Collect** - Return a specified ST\_Geometry value from a collection of other geometries.
  - **ST\_CoordDim** - Return the coordinate dimension of the ST\_Geometry value.
  - **ST\_CurveToLine** - Converts a CIRCULARSTRING/CURVEPOLYGON to a LINESTRING/POLYGON
  - **ST\_Distance** - For geometry type Returns the 2D Cartesian distance between two geometries in projected units (based on spatial ref). For geography type defaults to return minimum geodesic distance between two geographies in meters.
  - **ST\_Dump** - Returns a set of geometry\_dump (geom,path) rows, that make up a geometry g1.
  - **ST\_DumpPoints** - Returns a set of geometry\_dump (geom,path) rows of all points that make up a geometry.
  - **ST\_EndPoint** - Returns the last point of a LINESTRING or CIRCULARLINESTRING geometry as a POINT.
  - **ST\_EstimatedExtent** - Return the 'estimated' extent of the given spatial table. The estimated is taken from the geometry column's statistics. The current schema will be used if not specified.
  - **ST\_FlipCoordinates** - Returns a version of the given geometry with X and Y axis flipped. Useful for people who have built latitude/longitude features and need to fix them.
  - **ST\_Force2D** - Force the geometries into a "2-dimensional mode".
  - **ST\_ForceCurve** - Upcast a geometry into its curved type, if applicable.
  - **ST\_ForceSFS** - Force the geometries to use SFS 1.1 geometry types only.
-

- **ST\_Force3D** - Force the geometries into XYZ mode. This is an alias for ST\_Force3DZ.
  - **ST\_Force3DM** - Force the geometries into XYM mode.
  - **ST\_Force3DZ** - Force the geometries into XYZ mode.
  - **ST\_Force4D** - Force the geometries into XYZM mode.
  - **ST\_ForceCollection** - Convert the geometry into a GEOMETRYCOLLECTION.
  - **ST\_GeoHash** - Return a GeoHash representation of the geometry.
  - **ST\_GeogFromWKB** - Creates a geography instance from a Well-Known Binary geometry representation (WKB) or extended Well Known Binary (EWKB).
  - **ST\_GeomFromEWKB** - Return a specified ST\_Geometry value from Extended Well-Known Binary representation (EWKB).
  - **ST\_GeomFromEWKT** - Return a specified ST\_Geometry value from Extended Well-Known Text representation (EWKT).
  - **ST\_GeomFromText** - Return a specified ST\_Geometry value from Well-Known Text representation (WKT).
  - **ST\_GeomFromWKB** - Creates a geometry instance from a Well-Known Binary geometry representation (WKB) and optional SRID.
  - **ST\_GeometryN** - Return the 1-based Nth geometry if the geometry is a GEOMETRYCOLLECTION, (MULTI)POINT, (MULTI)LINEMULTICURVE or (MULTI)POLYGON, POLYHEDRALSURFACE Otherwise, return NULL.
  - **=** - Returns TRUE if A's bounding box is the same as B's. Uses double precision bounding box.
  - **&<l** - Returns TRUE if A's bounding box overlaps or is below B's.
  - **ST\_HasArc** - Returns true if a geometry or geometry collection contains a circular string
  - **ST\_IsClosed** - Returns TRUE if the LINESTRING's start and end points are coincident. For Polyhedral surface is closed (volumetric).
  - **ST\_IsCollection** - Returns TRUE if the argument is a collection (MULTI\*, GEOMETRYCOLLECTION, ...)
  - **ST\_IsEmpty** - Returns true if this Geometry is an empty geometrycollection, polygon, point etc.
  - **ST\_LineToCurve** - Converts a LINESTRING/POLYGON to a CIRCULARSTRING, CURVEPOLYGON
  - **ST\_MemSize** - Returns the amount of space (in bytes) the geometry takes.
  - **ST\_NPoints** - Return the number of points (vertexes) in a geometry.
  - **ST\_NRings** - If the geometry is a polygon or multi-polygon returns the number of rings.
  - **ST\_PointFromWKB** - Makes a geometry from WKB with the given SRID
  - **ST\_PointN** - Return the Nth point in the first LineString or circular LineString in the geometry. Negative values are counted backwards from the end of the LineString. Returns NULL if there is no linestring in the geometry.
  - **ST\_Points** - Returns a MultiPoint containing all of the coordinates of a geometry.
  - **ST\_Rotate** - Rotate a geometry rotRadians counter-clockwise about an origin.
  - **ST\_RotateZ** - Rotate a geometry rotRadians about the Z axis.
  - **ST\_SRID** - Returns the spatial reference identifier for the ST\_Geometry as defined in spatial\_ref\_sys table.
  - **ST\_Scale** - Scale a geometry by given factors.
  - **ST\_SetSRID** - Set the SRID on a geometry to a particular integer value.
  - **ST\_StartPoint** - Returns the first point of a LINESTRING geometry as a POINT.
  - **ST\_Summary** - Returns a text summary of the contents of the geometry.
-

- **ST\_SwapOrdinates** - Returns a version of the given geometry with given ordinate values swapped.
  - **ST\_TransScale** - Translate a geometry by given factors and offsets.
  - **ST\_Transform** - Return a new geometry with its coordinates transformed to a different spatial reference.
  - **ST\_Translate** - Translate a geometry by given offsets.
  - **ST\_XMax** - Returns X maxima of a bounding box 2d or 3d or a geometry.
  - **ST\_XMin** - Returns X minima of a bounding box 2d or 3d or a geometry.
  - **ST\_YMax** - Returns Y maxima of a bounding box 2d or 3d or a geometry.
  - **ST\_YMin** - Returns Y minima of a bounding box 2d or 3d or a geometry.
  - **ST\_ZMax** - Returns Z minima of a bounding box 2d or 3d or a geometry.
  - **ST\_ZMin** - Returns Z minima of a bounding box 2d or 3d or a geometry.
  - **ST\_Zmflag** - Returns ZM (dimension semantic) flag of the geometries as a small int. Values are: 0=2d, 1=3dm, 2=3dz, 3=4d.
  - **UpdateGeometrySRID** - Updates the SRID of all features in a geometry column, geometry\_columns metadata and srid. If it was enforced with constraints, the constraints will be updated with new srid constraint. If the old was enforced by type definition, the type definition will be changed.
  - **~(box2df,box2df)** - Returns TRUE if a 2D float precision bounding box (BOX2DF) contains another 2D float precision bounding box (BOX2DF).
  - **~(box2df,geometry)** - Returns TRUE if a 2D float precision bounding box (BOX2DF) contains a geometry's 2D bonding box.
  - **~(geometry,box2df)** - Returns TRUE if a geometry's 2D bonding box contains a 2D float precision bounding box (GIDX).
  - **&&** - Returns TRUE if A's 2D bounding box intersects B's 2D bounding box.
  - **&&&** - Returns TRUE if A's n-D bounding box intersects B's n-D bounding box.
  - **@(box2df,box2df)** - Returns TRUE if a 2D float precision bounding box (BOX2DF) is contained into another 2D float precision bounding box.
  - **@(box2df,geometry)** - Returns TRUE if a 2D float precision bounding box (BOX2DF) is contained into a geometry's 2D bounding box.
  - **@(geometry,box2df)** - Returns TRUE if a geometry's 2D bounding box is contained into a 2D float precision bounding box (BOX2DF).
  - **&&(box2df,box2df)** - Returns TRUE if two 2D float precision bounding boxes (BOX2DF) intersect each other.
  - **&&(box2df,geometry)** - Returns TRUE if a 2D float precision bounding box (BOX2DF) intersects a geometry's (cached) 2D bounding box.
  - **&&(geometry,box2df)** - Returns TRUE if a geometry's (cached) 2D bounding box intersects a 2D float precision bounding box (BOX2DF).
  - **&&&(geometry,gidx)** - Returns TRUE if a geometry's (cached) n-D bounding box intersects a n-D float precision bounding box (GIDX).
  - **&&&(gidx,geometry)** - Returns TRUE if a n-D float precision bounding box (GIDX) intersects a geometry's (cached) n-D bounding box.
  - **&&&(gidx,gidx)** - Returns TRUE if two n-D float precision bounding boxes (GIDX) intersect each other.
-

## 14.10 PostGIS Polyhedral Surface Support Functions

The functions given below are PostGIS functions that can use POLYHEDRALSURFACE, POLYHEDRALSURFACEM geometries

- **Box2D** - Returns a BOX2D representing the maximum extents of the geometry.
  - **Box3D** - Returns a BOX3D representing the maximum extents of the geometry.
  - **GeometryType** - Returns the type of the geometry as a string. Eg: 'LINESTRING', 'POLYGON', 'MULTIPOINT', etc.
  - **ST\_3DArea** - Computes area of 3D surface geometries. Will return 0 for solids.
  - **ST\_3DClosestPoint** - Returns the 3-dimensional point on g1 that is closest to g2. This is the first point of the 3D shortest line.
  - **ST\_3DDFullyWithin** - Returns true if all of the 3D geometries are within the specified distance of one another.
  - **ST\_3DDWithin** - For 3d (z) geometry type Returns true if two geometries 3d distance is within number of units.
  - **ST\_3DDifference** - Perform 3D difference
  - **ST\_3DDistance** - For geometry type Returns the 3-dimensional cartesian minimum distance (based on spatial ref) between two geometries in projected units.
  - **ST\_3DExtent** - an aggregate function that returns the box3D bounding box that bounds rows of geometries.
  - **ST\_3DIntersection** - Perform 3D intersection
  - **ST\_3DIntersects** - Returns TRUE if the Geometries "spatially intersect" in 3d - only for points, linestrings, polygons, polyhedral surface (area). With SFCGAL backend enabled also supports TINS
  - **ST\_3DLongestLine** - Returns the 3-dimensional longest line between two geometries
  - **ST\_3DMaxDistance** - For geometry type Returns the 3-dimensional cartesian maximum distance (based on spatial ref) between two geometries in projected units.
  - **ST\_3DShortestLine** - Returns the 3-dimensional shortest line between two geometries
  - **ST\_3DUnion** - Perform 3D union
  - **ST\_Accum** - Aggregate. Constructs an array of geometries.
  - **ST\_Affine** - Apply a 3d affine transformation to a geometry.
  - **ST\_ApproximateMedialAxis** - Compute the approximate medial axis of an areal geometry.
  - **ST\_Area** - Returns the area of the surface if it is a Polygon or MultiPolygon. For geometry, a 2D Cartesian area is determined with units specified by the SRID. For geography, area is determined on a curved surface with units in square meters.
  - **ST\_AsBinary** - Return the Well-Known Binary (WKB) representation of the geometry/geography without SRID meta data.
  - **ST\_AsEWKB** - Return the Well-Known Binary (WKB) representation of the geometry with SRID meta data.
  - **ST\_AsEWKT** - Return the Well-Known Text (WKT) representation of the geometry with SRID meta data.
  - **ST\_AsGML** - Return the geometry as a GML version 2 or 3 element.
  - **ST\_AsX3D** - Returns a Geometry in X3D xml node element format: ISO-IEC-19776-1.2-X3DEncodings-XML
  - **ST\_CoordDim** - Return the coordinate dimension of the ST\_Geometry value.
  - **ST\_Dimension** - The inherent dimension of this Geometry object, which must be less than or equal to the coordinate dimension.
  - **ST\_Dump** - Returns a set of geometry\_dump (geom,path) rows, that make up a geometry g1.
  - **ST\_DumpPoints** - Returns a set of geometry\_dump (geom,path) rows of all points that make up a geometry.
-

- **ST\_Expand** - Returns bounding box expanded in all directions from the bounding box of the input geometry. Uses double-precision
  - **ST\_Extent** - an aggregate function that returns the bounding box that bounds rows of geometries.
  - **ST\_Extrude** - Extrude a surface to a related volume
  - **ST\_FlipCoordinates** - Returns a version of the given geometry with X and Y axis flipped. Useful for people who have built latitude/longitude features and need to fix them.
  - **ST\_Force2D** - Force the geometries into a "2-dimensional mode".
  - **ST\_ForceLHR** - Force LHR orientation
  - **ST\_ForceRHR** - Force the orientation of the vertices in a polygon to follow the Right-Hand-Rule.
  - **ST\_ForceSFS** - Force the geometries to use SFS 1.1 geometry types only.
  - **ST\_Force3D** - Force the geometries into XYZ mode. This is an alias for ST\_Force3DZ.
  - **ST\_Force3DZ** - Force the geometries into XYZ mode.
  - **ST\_ForceCollection** - Convert the geometry into a GEOMETRYCOLLECTION.
  - **ST\_GeomFromEWKB** - Return a specified ST\_Geometry value from Extended Well-Known Binary representation (EWKB).
  - **ST\_GeomFromEWKT** - Return a specified ST\_Geometry value from Extended Well-Known Text representation (EWKT).
  - **ST\_GeomFromGML** - Takes as input GML representation of geometry and outputs a PostGIS geometry object
  - **ST\_GeometryN** - Return the 1-based Nth geometry if the geometry is a GEOMETRYCOLLECTION, (MULTI)POINT, (MULTI)LINE, MULTICURVE or (MULTI)POLYGON, POLYHEDRALSURFACE. Otherwise, return NULL.
  - **ST\_GeometryType** - Return the geometry type of the ST\_Geometry value.
  - **=** - Returns TRUE if A's bounding box is the same as B's. Uses double precision bounding box.
  - **&<l** - Returns TRUE if A's bounding box overlaps or is below B's.
  - **~=** - Returns TRUE if A's bounding box is the same as B's.
  - **ST\_IsClosed** - Returns TRUE if the LINESTRING's start and end points are coincident. For Polyhedral surface is closed (volumetric).
  - **ST\_IsPlanar** - Check if a surface is or not planar
  - **ST\_IsSolid** - Test if the geometry is a solid. No validity check is performed.
  - **ST\_MakeSolid** - Cast the geometry into a solid. No check is performed. To obtain a valid solid, the input geometry must be a closed Polyhedral Surface or a closed TIN.
  - **ST\_MemSize** - Returns the amount of space (in bytes) the geometry takes.
  - **ST\_NPoints** - Return the number of points (vertexes) in a geometry.
  - **ST\_NumGeometries** - If geometry is a GEOMETRYCOLLECTION (or MULTI\*) return the number of geometries, for single geometries will return 1, otherwise return NULL.
  - **ST\_NumPatches** - Return the number of faces on a Polyhedral Surface. Will return null for non-polyhedral geometries.
  - **ST\_PatchN** - Return the 1-based Nth geometry (face) if the geometry is a POLYHEDRALSURFACE, POLYHEDRALSURFACE. Otherwise, return NULL.
  - **ST\_RemoveRepeatedPoints** - Returns a version of the given geometry with duplicated points removed.
  - **ST\_Rotate** - Rotate a geometry rotRadians counter-clockwise about an origin.
-

- **ST\_RotateX** - Rotate a geometry rotRadians about the X axis.
  - **ST\_RotateY** - Rotate a geometry rotRadians about the Y axis.
  - **ST\_RotateZ** - Rotate a geometry rotRadians about the Z axis.
  - **ST\_Scale** - Scale a geometry by given factors.
  - **ST\_ShiftLongitude** - Toggle geometry coordinates between -180..180 and 0..360 ranges.
  - **ST\_StraightSkeleton** - Compute a straight skeleton from a geometry
  - **ST\_Summary** - Returns a text summary of the contents of the geometry.
  - **ST\_SwapOrdinates** - Returns a version of the given geometry with given ordinate values swapped.
  - **ST\_Tessellate** - Perform surface Tesselation of a polygon or polyhedralsurface and returns as a TIN or collection of TINS
  - **ST\_Transform** - Return a new geometry with its coordinates transformed to a different spatial reference.
  - **ST\_Volume** - Computes the volume of a 3D solid. If applied to surface (even closed) geometries will return 0.
  - **~(box2df,box2df)** - Returns TRUE if a 2D float precision bounding box (BOX2DF) contains another 2D float precision bounding box (BOX2DF).
  - **~(box2df,geometry)** - Returns TRUE if a 2D float precision bounding box (BOX2DF) contains a geometry's 2D bonding box.
  - **~(geometry,box2df)** - Returns TRUE if a geometry's 2D bonding box contains a 2D float precision bounding box (GIDX).
  - **&&** - Returns TRUE if A's 2D bounding box intersects B's 2D bounding box.
  - **&&&** - Returns TRUE if A's n-D bounding box intersects B's n-D bounding box.
  - **@(box2df,box2df)** - Returns TRUE if a 2D float precision bounding box (BOX2DF) is contained into another 2D float precision bounding box.
  - **@(box2df,geometry)** - Returns TRUE if a 2D float precision bounding box (BOX2DF) is contained into a geometry's 2D bounding box.
  - **@(geometry,box2df)** - Returns TRUE if a geometry's 2D bounding box is contained into a 2D float precision bounding box (BOX2DF).
  - **&&(box2df,box2df)** - Returns TRUE if two 2D float precision bounding boxes (BOX2DF) intersect each other.
  - **&&(box2df,geometry)** - Returns TRUE if a 2D float precision bounding box (BOX2DF) intersects a geometry's (cached) 2D bounding box.
  - **&&(geometry,box2df)** - Returns TRUE if a geometry's (cached) 2D bounding box intersects a 2D float precision bounding box (BOX2DF).
  - **&&&(geometry,gidx)** - Returns TRUE if a geometry's (cached) n-D bounding box intersects a n-D float precision bounding box (GIDX).
  - **&&&(gidx,geometry)** - Returns TRUE if a n-D float precision bounding box (GIDX) intersects a geometry's (cached) n-D bounding box.
  - **&&&(gidx,gidx)** - Returns TRUE if two n-D float precision bounding boxes (GIDX) intersect each other.
  - **postgis\_sfcgal\_version** - Returns the version of SFCGAL in use
-

### 14.11 PostGIS Function Support Matrix

Below is an alphabetical listing of spatial specific functions in PostGIS and the kinds of spatial types they work with or OGC/SQL compliance they try to conform to.

- A  means the function works with the type or subtype natively.
- A  means it works but with a transform cast built-in using cast to geometry, transform to a "best srid" spatial ref and then cast back. Results may not be as expected for large areas or areas at poles and may accumulate floating point junk.
- A  means the function works with the type because of a auto-cast to another such as to box3d rather than direct type support.
- A  means the function only available if PostGIS compiled with SFCGAL support.
- A  means the function support is provided by SFCGAL if PostGIS compiled with SFCGAL support, otherwise GEOS/built-in support.
- geom - Basic 2D geometry support (x,y).
- geog - Basic 2D geography support (x,y).
- 2.5D - basic 2D geometries in 3 D/4D space (has Z or M coord).
- PS - Polyhedral surfaces
- T - Triangles and Triangulated Irregular Network surfaces (TIN)

## 14.12 New, Enhanced or changed PostGIS Functions

**Note**  
PostGIS 2.3.0: PostgreSQL 9.6+ support for parallel queries.

**Note**  
PostGIS 2.3.0: PostgreSQL 9.4+ support for BRIN indexes. Refer to Section 4.6.2.

**Note**  
PostGIS 2.3.0: Tiger Geocoder upgraded to work with TIGER 2016 data.

**Note**  
PostGIS 2.3.4: All 3D related including SFCGAL marked as parallel safe.

### 14.12.1 PostGIS Functions new or enhanced in 2.3

The functions given below are PostGIS functions that were added or enhanced.

Functions new in PostGIS 2.3

- **ST\_GeometricMedian** - Availability: 2.3.0 Returns the geometric median of a MultiPoint.
- **&&&(geometry,gidx)** - Availability: 2.3.0 support for Block Range INdexes (BRIN) was introduced. Requires PostgreSQL 9.5+. Returns TRUE if a geometry's (cached) n-D bounding box intersects a n-D float precision bounding box (GIDX).
- **&&&(gidx,geometry)** - Availability: 2.3.0 support for Block Range INdexes (BRIN) was introduced. Requires PostgreSQL 9.5+. Returns TRUE if a n-D float precision bounding box (GIDX) intersects a geometry's (cached) n-D bounding box.
- **&&&(gidx,gidx)** - Availability: 2.3.0 support for Block Range INdexes (BRIN) was introduced. Requires PostgreSQL 9.5+. Returns TRUE if two n-D float precision bounding boxes (GIDX) intersect each other.
- **&&(box2df,box2df)** - Availability: 2.3.0 support for Block Range INdexes (BRIN) was introduced. Requires PostgreSQL 9.5+. Returns TRUE if two 2D float precision bounding boxes (BOX2DF) intersect each other.
- **&&(box2df,geometry)** - Availability: 2.3.0 support for Block Range INdexes (BRIN) was introduced. Requires PostgreSQL 9.5+. Returns TRUE if a 2D float precision bounding box (BOX2DF) intersects a geometry's (cached) 2D bounding box.
- **&&(geometry,box2df)** - Availability: 2.3.0 support for Block Range INdexes (BRIN) was introduced. Requires PostgreSQL 9.5+. Returns TRUE if a geometry's (cached) 2D bounding box intersects a 2D float precision bounding box (BOX2DF).
- **@(box2df,box2df)** - Availability: 2.3.0 support for Block Range INdexes (BRIN) was introduced. Requires PostgreSQL 9.5+. Returns TRUE if a 2D float precision bounding box (BOX2DF) is contained into another 2D float precision bounding box.
- **@(box2df,geometry)** - Availability: 2.3.0 support for Block Range INdexes (BRIN) was introduced. Requires PostgreSQL 9.5+. Returns TRUE if a 2D float precision bounding box (BOX2DF) is contained into a geometry's 2D bounding box.
- **@(geometry,box2df)** - Availability: 2.3.0 support for Block Range INdexes (BRIN) was introduced. Requires PostgreSQL 9.5+. Returns TRUE if a geometry's 2D bounding box is contained into a 2D float precision bounding box (BOX2DF).
- **Populate\_Topology\_Layer** - Availability: 2.3.0 Adds missing entries to topology.layer table by reading metadata from topo tables.
- **ST\_ClusterDBSCAN** - Availability: 2.3.0 - requires GEOS Windowing function that returns integer id for the cluster each input geometry is in based on 2D implementation of Density-based spatial clustering of applications with noise (DBSCAN) algorithm.
- **ST\_ClusterKMeans** - Availability: 2.3.0 - requires GEOS Windowing function that returns integer id for the cluster each input geometry is in.
- **ST\_GeneratePoints** - Availability: 2.3.0 Converts a polygon or multi-polygon into a multi-point composed of randomly location points within the original areas.
- **ST\_MakeLine** - Availability: 2.3.0 - Support for multipoint input elements was introduced Creates a Linestring from point, multipoint, or line geometries.
- **ST\_MinimumClearance** - Availability: 2.3.0 - requires GEOS >= 3.6.0 Returns the minimum clearance of a geometry, a measure of a geometry's robustness.
- **ST\_MinimumClearanceLine** - Availability: 2.3.0 - requires GEOS >= 3.6.0 Returns the two-point LineString spanning a geometry's minimum clearance.
- **ST\_Points** - Availability: 2.3.0 Returns a MultiPoint containing all of the coordinates of a geometry.
- **ST\_VoronoiLines** - Availability: 2.3.0 - requires GEOS >= 3.5.0. Returns the boundaries between the cells of the Voronoi diagram constructed from the vertices of a geometry.
- **ST\_VoronoiPolygons** - Availability: 2.3.0 - requires GEOS >= 3.5.0. Returns the cells of the Voronoi diagram constructed from the vertices of a geometry.

- **ST\_WrapX** - Availability: 2.3.0 Wrap a geometry around an X value.
- **TopoGeom\_addElement** - Availability: 2.3 Add an element to the definition of a TopoGeometry
- **TopoGeom\_remElement** - Availability: 2.3 Remove an element from the definition of a TopoGeometry
- **~(box2df,box2df)** - Availability: 2.3.0 support for Block Range INdexes (BRIN) was introduced. Requires PostgreSQL 9.5+. Returns TRUE if a 2D float precision bounding box (BOX2DF) contains another 2D float precision bounding box (BOX2DF).
- **~(box2df,geometry)** - Availability: 2.3.0 support for Block Range INdexes (BRIN) was introduced. Requires PostgreSQL 9.5+. Returns TRUE if a 2D float precision bounding box (BOX2DF) contains a geometry's 2D bonding box.
- **~(geometry,box2df)** - Availability: 2.3.0 support for Block Range INdexes (BRIN) was introduced. Requires PostgreSQL 9.5+. Returns TRUE if a geometry's 2D bonding box contains a 2D float precision bounding box (GIDX).

The functions given below are PostGIS functions that are enhanced in PostGIS 2.3.

- **ST\_Contains** - Enhanced: 2.3.0 Enhancement to PIP short-circuit extended to support MultiPoints with few points. Prior versions only supported point in polygon.
- **ST\_Covers** - Enhanced: 2.3.0 Enhancement to PIP short-circuit for geometry extended to support MultiPoints with few points. Prior versions only supported point in polygon.
- **ST\_Expand** - Enhanced: 2.3.0 support was added to expand a box by different amounts in different dimensions.
- **ST\_Intersects** - Enhanced: 2.3.0 Enhancement to PIP short-circuit extended to support MultiPoints with few points. Prior versions only supported point in polygon.
- **ST\_Segmentize** - Enhanced: 2.3.0 Segmentize geography now uses equal length segments
- **ST\_Transform** - Enhanced: 2.3.0 support for direct PROJ.4 text was introduced.
- **ST\_Within** - Enhanced: 2.3.0 Enhancement to PIP short-circuit for geometry extended to support MultiPoints with few points. Prior versions only supported point in polygon.

### 14.12.2 PostGIS Functions new or enhanced in 2.2

The functions given below are PostGIS functions that were added or enhanced.

**Note**

postgis\_sfcgal now can be installed as an extension using CREATE EXTENSION postgis\_sfcgal;

---

**Note**

PostGIS 2.2.0: Tiger Geocoder upgraded to work with TIGER 2015 data.

---

**Note**

address\_standardizer, address\_standardizer\_data\_us extensions for standardizing address data refer to [Chapter 12](#) for details.

---

**Note**

Many functions in topology rewritten as C functions for increased performance.

---

## Functions new in PostGIS 2.2

- `<<#>>` - Availability: 2.2.0 -- KNN only available for PostgreSQL 9.1+ Returns the n-D distance between A and B bounding boxes.
  - `<<->>` - Availability: 2.2.0 -- KNN only available for PostgreSQL 9.1+ Returns the n-D distance between the centroids of A and B boundingboxes.
  - `ST_3DDifference` - Availability: 2.2.0 Perform 3D difference
  - `ST_3DUnion` - Availability: 2.2.0 Perform 3D union
  - `ST_ApproximateMedialAxis` - Availability: 2.2.0 Compute the approximate medial axis of an areal geometry.
  - `ST_AsEncodedPolyline` - Availability: 2.2.0 Returns an Encoded Polyline from a LineString geometry.
  - `ST_AsTWKB` - Availability: 2.2.0 Returns the geometry as TWKB, aka "Tiny Well-Known Binary"
  - `ST_BoundingDiagonal` - Availability: 2.2.0 Returns the diagonal of the supplied geometry's bounding box.
  - `ST_CPAWithin` - Availability: 2.2.0 Returns true if the trajectories' closest points of approach are within the specified distance.
  - `ST_ClipByBox2D` - Availability: 2.2.0 - requires GEOS >= 3.5.0. Returns the portion of a geometry falling within a rectangle.
  - `ST_ClosestPointOfApproach` - Availability: 2.2.0 Returns the measure at which points interpolated along two lines are closest.
  - `ST_ClusterIntersecting` - Availability: 2.2.0 - requires GEOS Aggregate. Returns an array with the connected components of a set of geometries
  - `ST_ClusterWithin` - Availability: 2.2.0 - requires GEOS Aggregate. Returns an array of GeometryCollections, where each GeometryCollection represents a set of geometries separated by no more than the specified distance.
  - `ST_CountAgg` - Availability: 2.2.0 Aggregate. Returns the number of pixels in a given band of a set of rasters. If no band is specified defaults to band 1. If `exclude_nodata_value` is set to true, will only count pixels that are not equal to the NODATA value.
  - `ST_CreateOverview` - Availability: 2.2.0 Create an reduced resolution version of a given raster coverage.
  - `ST_DistanceCPA` - Availability: 2.2.0 Returns the distance between closest points of approach in two trajectories.
  - `ST_ForceCurve` - Availability: 2.2.0 Upcast a geometry into its curved type, if applicable.
  - `ST_IsPlanar` - Availability: 2.2.0: This was documented in 2.1.0 but got accidentally left out in 2.1 release. Check if a surface is or not planar
  - `ST_IsSolid` - Availability: 2.2.0 Test if the geometry is a solid. No validity check is performed.
  - `ST_IsValidTrajectory` - Availability: 2.2.0 Returns true if the geometry is a valid trajectory.
  - `ST_LineFromEncodedPolyline` - Availability: 2.2.0 Creates a LineString from an Encoded Polyline.
  - `ST_MakeSolid` - Availability: 2.2.0 Cast the geometry into a solid. No check is performed. To obtain a valid solid, the input geometry must be a closed Polyhedral Surface or a closed TIN.
  - `ST_MapAlgebra` - Availability: 2.2.0: Ability to add a mask Callback function version - Returns a one-band raster given one or more input rasters, band indexes and one user-specified callback function.
  - `ST_MemSize` - Availability: 2.2.0 Returns the amount of space (in bytes) the raster takes.
  - `ST_RemoveRepeatedPoints` - Availability: 2.2.0 Returns a version of the given geometry with duplicated points removed.
  - `ST_Retile` - Availability: 2.2.0 Return a set of configured tiles from an arbitrarily tiled raster coverage.
  - `ST_SetEffectiveArea` - Availability: 2.2.0 Sets the effective area for each vertex, storing the value in the M ordinate. A simplified geometry can then be generated by filtering on the M ordinate.
-

- **ST\_SimplifyVW** - Availability: 2.2.0 Returns a "simplified" version of the given geometry using the Visvalingam-Whyatt algorithm
- **ST\_Subdivide** - Availability: 2.2.0 requires GEOS >= 3.5.0. Returns a set of geometry where no geometry in the set has more than the specified number of vertices.
- **ST\_SummaryStatsAgg** - Availability: 2.2.0 Aggregate. Returns summarystats consisting of count, sum, mean, stddev, min, max for a given raster band of a set of raster. Band 1 is assumed is no band is specified.
- **ST\_SwapOrdinates** - Availability: 2.2.0 Returns a version of the given geometry with given ordinate values swapped.
- **ST\_Volume** - Availability: 2.2.0 Computes the volume of a 3D solid. If applied to surface (even closed) geometries will return 0.
- **parse\_address** - Availability: 2.2.0 Takes a 1 line address and breaks into parts
- **postgis.enable\_outdb\_rasters** - Availability: 2.2.0 A boolean configuration option to enable access to out-db raster bands.
- **postgis.gdal\_datapath** - Availability: 2.2.0 A configuration option to assign the value of GDAL's GDAL\_DATA option. If not set, the environmentally set GDAL\_DATA variable is used.
- **postgis.gdal\_enabled\_drivers** - Availability: 2.2.0 A configuration option to set the enabled GDAL drivers in the PostGIS environment. Affects the GDAL configuration variable GDAL\_SKIP.
- **standardize\_address** - Availability: 2.2.0 Returns an stdaddr form of an input address utilizing lex, gaz, and rule tables.
- **l=** - Availability: 2.2.0. Index-supported only available for PostgreSQL 9.5+ Returns the distance between A and B trajectories at their closest point of approach.

The functions given below are PostGIS functions that are enhanced in PostGIS 2.2.

- **AsTopoJSON** - Enhanced: 2.2.1 added support for puntal inputs
- **ST\_Area** - Enhanced: 2.2.0 - measurement on spheroid performed with GeographicLib for improved accuracy and robustness. Requires Proj >= 4.9.0 to take advantage of the new feature.
- **ST\_AsX3D** - Enhanced: 2.2.0: Support for GeoCoordinates and axis (x/y, long/lat) flipping. Look at options for details.
- **ST\_Azimuth** - Enhanced: 2.2.0 measurement on spheroid performed with GeographicLib for improved accuracy and robustness. Requires Proj >= 4.9.0 to take advantage of the new feature.
- **ST\_Distance** - Enhanced: 2.2.0 - measurement on spheroid performed with GeographicLib for improved accuracy and robustness. Requires Proj >= 4.9.0 to take advantage of the new feature.
- **ST\_Scale** - Enhanced: 2.2.0 support for scaling all dimension (geometry parameter) was introduced.
- **ST\_Summary** - Enhanced: 2.2.0 Added support for TIN and Curves
- **<->** - Enhanced: 2.2.0 -- True KNN ("K nearest neighbor") behavior for geometry and geography for PostgreSQL 9.5+. Note for geography KNN is based on sphere rather than spheroid. For PostgreSQL 9.4 and below, geography support is new but only supports centroid box.

### 14.12.3 PostGIS functions breaking changes in 2.2

The functions given below are PostGIS functions that have possibly breaking changes in PostGIS 2.2. If you use any of these, you may need to check your existing code.

- **Get\_Geocode\_Setting** - Changed: 2.2.0 : default settings are now kept in a table called geocode\_settings\_default. Use customized settingsa are in geocode\_settings and only contain those that have been set by user.
- **ST\_3DClosestPoint** - Changed: 2.2.0 - if 2 2D geometries are input, a 2D point is returned (instead of old behavior assuming 0 for missing Z). In case of 2D and 3D, Z is no longer assumed to be 0 for missing Z.

- **ST\_3DDistance** - Changed: 2.2.0 - In case of 2D and 3D, Z is no longer assumed to be 0 for missing Z.
- **ST\_3DLongestLine** - Changed: 2.2.0 - if 2 2D geometries are input, a 2D point is returned (instead of old behavior assuming 0 for missing Z). In case of 2D and 3D, Z is no longer assumed to be 0 for missing Z.
- **ST\_3DMaxDistance** - Changed: 2.2.0 - In case of 2D and 3D, Z is no longer assumed to be 0 for missing Z.
- **ST\_3DShortestLine** - Changed: 2.2.0 - if 2 2D geometries are input, a 2D point is returned (instead of old behavior assuming 0 for missing Z). In case of 2D and 3D, Z is no longer assumed to be 0 for missing Z.
- **ST\_DistanceSphere** - Changed: 2.2.0 In prior versions this used to be called ST\_Distance\_Sphere
- **ST\_DistanceSpheroid** - Changed: 2.2.0 In prior versions this used to be called ST\_Distance\_Spheroid
- **ST\_Equals** - Changed: 2.2.0 Returns true even for invalid geometries if they are binary equal
- **ST\_LengthSpheroid** - Changed: 2.2.0 In prior versions this used to be called ST\_Length\_Spheroid and used to have a ST\_3DLength\_Spheroid alias
- **ST\_MemSize** - Changed: 2.2.0 name changed to ST\_MemSize to follow naming convention. In prior versions this function was called ST\_Mem\_Size, old name deprecated though still available.
- **ST\_PointInsideCircle** - Changed: 2.2.0 In prior versions this used to be called ST\_Point\_Inside\_Circle
- **ST\_Split** - Changed: 2.2.0 support for splitting a line by a multiline, a multipoint or (multi)polygon boundary was introduced.
- **ValidateTopology** - Changed: 2.2.0 values for id1 and id2 were swapped for 'edge crosses node' to be consistent with error description.
- **<->** - Changed: 2.2.0 -- For PostgreSQL 9.5 users, old Hybrid syntax may be slower, so you'll want to get rid of that hack if you are running your code only on PostGIS 2.2+ 9.5+. See examples below.

#### 14.12.4 PostGIS Functions new or enhanced in 2.1

The functions given below are PostGIS functions that were added or enhanced.

##### Note

More Topology performance Improvements. Please refer to Chapter 11 for more details.

##### Note

Bug fixes (particularly with handling of out-of-band rasters), many new functions (often shortening code you have to write to accomplish a common task) and massive speed improvements to raster functionality. Refer to Chapter 9 for more details.

##### Note

PostGIS 2.1.0: Tiger Geocoder upgraded to work with TIGER 2012 census data. `geocode_settings` added for debugging and tweaking rating preferences, loader made less greedy, now only downloads tables to be loaded. PostGIS 2.1.1: Tiger Geocoder upgraded to work with TIGER 2013 data. Please refer to Section 13.1 for more details.

Functions new in PostGIS 2.1

- **AsTopoJSON** - Availability: 2.1.0 Returns the TopoJSON representation of a topogeometry.
- **Drop\_Nation\_Tables\_Generate\_Script** - Availability: 2.1.0 Generates a script that drops all tables in the specified schema that start with `county_all`, `state_all` or `state code` followed by `county` or `state`.

- **Get\_Geocode\_Setting** - Availability: 2.1.0 Returns value of specific setting stored in tiger.geocode\_settings table.
  - **Loader\_Generate\_Nation\_Script** - Availability: 2.1.0 Generates a shell script for the specified platform that loads in the county and state lookup tables.
  - **Page\_Normalize\_Address** - Availability: 2.1.0 Given a textual street address, returns a composite norm\_addy type that has road suffix, prefix and type standardized, street, streetname etc. broken into separate fields. This function will work with just the lookup data packaged with the tiger\_geocoder (no need for tiger census data). Requires address\_standardizer extension.
  - **ST\_3DArea** - Availability: 2.1.0 Computes area of 3D surface geometries. Will return 0 for solids.
  - **ST\_3DIntersection** - Availability: 2.1.0 Perform 3D intersection
  - **ST\_Box2dFromGeoHash** - Availability: 2.1.0 Return a BOX2D from a GeoHash string.
  - **ST\_ColorMap** - Availability: 2.1.0 Creates a new raster of up to four 8BUI bands (grayscale, RGB, RGBA) from the source raster and a specified band. Band 1 is assumed if not specified.
  - **ST\_Contains** - Availability: 2.1.0 Return true if no points of raster rastB lie in the exterior of raster rastA and at least one point of the interior of rastB lies in the interior of rastA.
  - **ST\_ContainsProperly** - Availability: 2.1.0 Return true if rastB intersects the interior of rastA but not the boundary or exterior of rastA.
  - **ST\_CoveredBy** - Availability: 2.1.0 Return true if no points of raster rastA lie outside raster rastB.
  - **ST\_Covers** - Availability: 2.1.0 Return true if no points of raster rastB lie outside raster rastA.
  - **ST\_DFullyWithin** - Availability: 2.1.0 Return true if rasters rastA and rastB are fully within the specified distance of each other.
  - **ST\_DWithin** - Availability: 2.1.0 Return true if rasters rastA and rastB are within the specified distance of each other.
  - **ST\_DelaunayTriangles** - Availability: 2.1.0 - requires GEOS >= 3.4.0. Return a Delaunay triangulation around the given input points.
  - **ST\_Disjoint** - Availability: 2.1.0 Return true if raster rastA does not spatially intersect rastB.
  - **ST\_DumpValues** - Availability: 2.1.0 Get the values of the specified band as a 2-dimension array.
  - **ST\_Extrude** - Availability: 2.1.0 Extrude a surface to a related volume
  - **ST\_ForceLHR** - Availability: 2.1.0 Force LHR orientation
  - **ST\_FromGDALRaster** - Availability: 2.1.0 Returns a raster from a supported GDAL raster file.
  - **ST\_GeomFromGeoHash** - Availability: 2.1.0 Return a geometry from a GeoHash string.
  - **ST\_InvDistWeight4ma** - Availability: 2.1.0 Raster processing function that interpolates a pixel's value from the pixel's neighborhood.
  - **ST\_MapAlgebra** - Availability: 2.1.0 Callback function version - Returns a one-band raster given one or more input rasters, band indexes and one user-specified callback function.
  - **ST\_MapAlgebra** - Availability: 2.1.0 Expression version - Returns a one-band raster given one or two input rasters, band indexes and one or more user-specified SQL expressions.
  - **ST\_MinConvexHull** - Availability: 2.1.0 Return the convex hull geometry of the raster excluding NODATA pixels.
  - **ST\_MinDist4ma** - Availability: 2.1.0 Raster processing function that returns the minimum distance (in number of pixels) between the pixel of interest and a neighboring pixel with value.
  - **ST\_MinkowskiSum** - Availability: 2.1.0 Performs Minkowski sum
  - **ST\_NearestValue** - Availability: 2.1.0 Returns the nearest non-NODATA value of a given band's pixel specified by a columnx and rowy or a geometric point expressed in the same spatial reference coordinate system as the raster.
-

- **ST\_Neighborhood** - Availability: 2.1.0 Returns a 2-D double precision array of the non-NODATA values around a given band's pixel specified by either a columnX and rowY or a geometric point expressed in the same spatial reference coordinate system as the raster.
  - **ST\_NotSameAlignmentReason** - Availability: 2.1.0 Returns text stating if rasters are aligned and if not aligned, a reason why.
  - **ST\_Orientation** - Availability: 2.1.0 Determine surface orientation
  - **ST\_Overlaps** - Availability: 2.1.0 Return true if raster rastA and rastB intersect but one does not completely contain the other.
  - **ST\_PixelAsCentroid** - Availability: 2.1.0 Returns the centroid (point geometry) of the area represented by a pixel.
  - **ST\_PixelAsCentroids** - Availability: 2.1.0 Returns the centroid (point geometry) for each pixel of a raster band along with the value, the X and the Y raster coordinates of each pixel. The point geometry is the centroid of the area represented by a pixel.
  - **ST\_PixelAsPoint** - Availability: 2.1.0 Returns a point geometry of the pixel's upper-left corner.
  - **ST\_PixelAsPoints** - Availability: 2.1.0 Returns a point geometry for each pixel of a raster band along with the value, the X and the Y raster coordinates of each pixel. The coordinates of the point geometry are of the pixel's upper-left corner.
  - **ST\_PixelOfValue** - Availability: 2.1.0 Get the columnx, rowy coordinates of the pixel whose value equals the search value.
  - **ST\_PointFromGeoHash** - Availability: 2.1.0 Return a point from a GeoHash string.
  - **ST\_RasterToWorldCoord** - Availability: 2.1.0 Returns the raster's upper left corner as geometric X and Y (longitude and latitude) given a column and row. Column and row starts at 1.
  - **ST\_Resize** - Availability: 2.1.0 Requires GDAL 1.6.1+ Resize a raster to a new width/height
  - **ST\_Roughness** - Availability: 2.1.0 Returns a raster with the calculated "roughness" of a DEM.
  - **ST\_SetValues** - Availability: 2.1.0 Returns modified raster resulting from setting the values of a given band.
  - **ST\_Simplify** - Availability: 2.1.0 Returns a "simplified" geometry version of the given TopoGeometry using the Douglas-Peucker algorithm.
  - **ST\_StraightSkeleton** - Availability: 2.1.0 Compute a straight skeleton from a geometry
  - **ST\_Summary** - Availability: 2.1.0 Returns a text summary of the contents of the raster.
  - **ST\_TPI** - Availability: 2.1.0 Returns a raster with the calculated Topographic Position Index.
  - **ST\_TRI** - Availability: 2.1.0 Returns a raster with the calculated Terrain Ruggedness Index.
  - **ST\_Tessellate** - Availability: 2.1.0 Perform surface Tesselation of a polygon or polyhedralsurface and returns as a TIN or collection of TINS
  - **ST\_Tile** - Availability: 2.1.0 Returns a set of rasters resulting from the split of the input raster based upon the desired dimensions of the output rasters.
  - **ST\_Touches** - Availability: 2.1.0 Return true if raster rastA and rastB have at least one point in common but their interiors do not intersect.
  - **ST\_Union** - Availability: 2.1.0 ST\_Union(rast, unionarg) variant was introduced. Returns the union of a set of raster tiles into a single raster composed of 1 or more bands.
  - **ST\_Within** - Availability: 2.1.0 Return true if no points of raster rastA lie in the exterior of raster rastB and at least one point of the interior of rastA lies in the interior of rastB.
  - **ST\_WorldToRasterCoord** - Availability: 2.1.0 Returns the upper left corner as column and row given geometric X and Y (longitude and latitude) or a point geometry expressed in the spatial reference coordinate system of the raster.
  - **Set\_Geocode\_Setting** - Availability: 2.1.0 Sets a setting that affects behavior of geocoder functions.
  - **UpdateRasterSRID** - Availability: 2.1.0 Change the SRID of all rasters in the user-specified column and table.
-

- **clearTopoGeom** - Availability: 2.1 Clears the content of a topo geometry
- **postgis.backend** - Availability: 2.1.0 The backend to service a function where GEOS and SFCGAL overlap. Options: geos or sfcgal. Defaults to geos.
- **postgis\_sfcgal\_version** - Availability: 2.1.0 Returns the version of SFCGAL in use

The functions given below are PostGIS functions that are enhanced in PostGIS 2.1.

- **ST\_AddBand** - Enhanced: 2.1.0 support for addbandarg added.
  - **ST\_AddBand** - Enhanced: 2.1.0 support for new out-db bands added.
  - **ST\_AsBinary** - Enhanced: 2.1.0 Addition of outasin
  - **ST\_Aspect** - Enhanced: 2.1.0 Uses ST\_MapAlgebra() and added optional interpolate\_nodata function parameter
  - **ST\_Clip** - Enhanced: 2.1.0 Rewritten in C
  - **ST\_Distinct4ma** - Enhanced: 2.1.0 Addition of Variant 2
  - **ST\_HillShade** - Enhanced: 2.1.0 Uses ST\_MapAlgebra() and added optional interpolate\_nodata function parameter
  - **ST\_Max4ma** - Enhanced: 2.1.0 Addition of Variant 2
  - **ST\_Mean4ma** - Enhanced: 2.1.0 Addition of Variant 2
  - **ST\_Min4ma** - Enhanced: 2.1.0 Addition of Variant 2
  - **ST\_PixelAsPolygons** - Enhanced: 2.1.0 exclude\_nodata\_value optional argument was added.
  - **ST\_Polygon** - Enhanced: 2.1.0 Improved Speed (fully C-Based) and the returning multipolygon is ensured to be valid.
  - **ST\_Range4ma** - Enhanced: 2.1.0 Addition of Variant 2
  - **ST\_SameAlignment** - Enhanced: 2.1.0 addition of Aggegrate variant
  - **ST\_SetGeoReference** - Enhanced: 2.1.0 Addition of ST\_SetGeoReference(raster, double precision, ...) variant
  - **ST\_SetValue** - Enhanced: 2.1.0 Geometry variant of ST\_SetValue() now supports any geometry type, not just point. The geometry variant is a wrapper around the geomval[] variant of ST\_SetValues()
  - **ST\_Slope** - Enhanced: 2.1.0 Uses ST\_MapAlgebra() and added optional units, scale, interpolate\_nodata function parameters
  - **ST\_StdDev4ma** - Enhanced: 2.1.0 Addition of Variant 2
  - **ST\_Sum4ma** - Enhanced: 2.1.0 Addition of Variant 2
  - **ST\_Transform** - Enhanced: 2.1.0 Addition of ST\_Transform(rast, alignto) variant
  - **ST\_Union** - Enhanced: 2.1.0 Improved Speed (fully C-Based).
  - **ST\_Union** - Enhanced: 2.1.0 ST\_Union(rast) (variant 1) unions all bands of all input rasters. Prior versions of PostGIS assumed the first band.
  - **ST\_Union** - Enhanced: 2.1.0 ST\_Union(rast, uniontype) (variant 4) unions all bands of all input rasters.
  - **ST\_AsGML** - Enhanced: 2.1.0 id support was introduced, for GML 3.
  - **ST\_Boundary** - Enhanced: 2.1.0 support for Triangle was introduced
  - **ST\_DWithin** - Enhanced: 2.1.0 improved speed for geography. See Making Geography faster for details.
  - **ST\_DWithin** - Enhanced: 2.1.0 support for curved geometries was introduced.
  - **ST\_Distance** - Enhanced: 2.1.0 improved speed for geography. See Making Geography faster for details.
-

- **ST\_Distance** - Enhanced: 2.1.0 - support for curved geometries was introduced.
- **ST\_DumpPoints** - Enhanced: 2.1.0 Faster speed. Reimplemented as native-C.
- **ST\_MakeValid** - Enhanced: 2.1.0 added support for GEOMETRYCOLLECTION and MULTIPOINT.
- **ST\_Segmentize** - Enhanced: 2.1.0 support for geography was introduced.
- **ST\_Summary** - Enhanced: 2.1.0 S flag to denote if has a known spatial reference system
- **toTopoGeom** - Enhanced: 2.1.0 adds the version taking an existing TopoGeometry.

#### 14.12.5 PostGIS functions breaking changes in 2.1

The functions given below are PostGIS functions that have possibly breaking changes in PostGIS 2.1. If you use any of these, you may need to check your existing code.

- **ST\_Aspect** - Changed: 2.1.0 In prior versions, return values were in radians. Now, return values default to degrees
- **ST\_HillShade** - Changed: 2.1.0 In prior versions, azimuth and altitude were expressed in radians. Now, azimuth and altitude are expressed in degrees
- **ST\_Intersects** - Changed: 2.1.0 The behavior of the ST\_Intersects(raster, geometry) variants changed to match that of ST\_Intersects(geometry, raster).
- **ST\_PixelAsCentroids** - Changed: 2.1.1 Changed behavior of exclude\_nodata\_value.
- **ST\_PixelAsPoints** - Changed: 2.1.1 Changed behavior of exclude\_nodata\_value.
- **ST\_PixelAsPolygons** - Changed: 2.1.1 Changed behavior of exclude\_nodata\_value.
- **ST\_Polygon** - Changed: 2.1.0 In prior versions would sometimes return a polygon, changed to always return multipolygon.
- **ST\_RasterToWorldCoordX** - Changed: 2.1.0 In prior versions, this was called ST\_Raster2WorldCoordX
- **ST\_RasterToWorldCoordY** - Changed: 2.1.0 In prior versions, this was called ST\_Raster2WorldCoordY
- **ST\_Resample** - Changed: 2.1.0 Parameter srid removed. Variants with a reference raster no longer applies the reference raster's SRID. Use ST\_Transform() to reproject raster. Works on rasters with no SRID.
- **ST\_Rescale** - Changed: 2.1.0 Works on rasters with no SRID
- **ST\_Reskew** - Changed: 2.1.0 Works on rasters with no SRID
- **ST\_Slope** - Changed: 2.1.0 In prior versions, return values were in radians. Now, return values default to degrees
- **ST\_SnapToGrid** - Changed: 2.1.0 Works on rasters with no SRID
- **ST\_WorldToRasterCoordX** - Changed: 2.1.0 In prior versions, this was called ST\_World2RasterCoordX
- **ST\_WorldToRasterCoordY** - Changed: 2.1.0 In prior versions, this was called ST\_World2RasterCoordY
- **ST\_EstimatedExtent** - Changed: 2.1.0. Up to 2.0.x this was called ST\_Estimated\_Extent.
- **ST\_Force2D** - Changed: 2.1.0. Up to 2.0.x this was called ST\_Force\_2D.
- **ST\_Force3D** - Changed: 2.1.0. Up to 2.0.x this was called ST\_Force\_3D.
- **ST\_Force3DM** - Changed: 2.1.0. Up to 2.0.x this was called ST\_Force\_3DM.
- **ST\_Force3DZ** - Changed: 2.1.0. Up to 2.0.x this was called ST\_Force\_3DZ.
- **ST\_Force4D** - Changed: 2.1.0. Up to 2.0.x this was called ST\_Force\_4D.
- **ST\_ForceCollection** - Changed: 2.1.0. Up to 2.0.x this was called ST\_Force\_Collection.

- **ST\_LineInterpolatePoint** - Changed: 2.1.0. Up to 2.0.x this was called ST\_Line\_Interpolate\_Point.
- **ST\_LineLocatePoint** - Changed: 2.1.0. Up to 2.0.x this was called ST\_Line\_Locate\_Point.
- **ST\_LineSubstring** - Changed: 2.1.0. Up to 2.0.x this was called ST\_Line\_Substring.
- **ST\_Segmentize** - Changed: 2.1.0 As a result of the introduction of geography support: The construct `SELECT ST_Segmentize('LINESTRING(2 3 4)',0.5)`; will result in ambiguous function error. You need to have properly typed object e.g. a geometry/geography column, use `ST_GeomFromText`, `ST_GeogFromText` or `SELECT ST_Segmentize('LINESTRING(1 2, 3 4)::geometry,0.5)`;

### 14.12.6 PostGIS Functions new, behavior changed, or enhanced in 2.0

The functions given below are PostGIS functions that were added, enhanced, or have Section 14.12.7 breaking changes in 2.0 releases.

New geometry types: TIN and Polyhedral surfaces was introduced in 2.0

#### Note

Greatly improved support for Topology. Please refer to Chapter 11 for more details.

#### Note

In PostGIS 2.0, raster type and raster functionality has been integrated. There are way too many new raster functions to list here and all are new so please refer to Chapter 9 for more details of the raster functions available. Earlier pre-2.0 versions had `raster_columns`/`raster_overviews` as real tables. These were changed to views before release. Functions such as `ST_AddRasterColumn` were removed and replaced with **AddRasterConstraints**, **DropRasterConstraints** as a result some apps that created raster tables may need changing.

#### Note

Tiger Geocoder upgraded to work with TIGER 2010 census data and now included in the core PostGIS documentation. A reverse geocoder function was also added. Please refer to Section 13.1 for more details.

- **&&** - Availability: 2.0.0 Returns TRUE if A's bounding box intersects B's bounding box.
- **&&&** - Availability: 2.0.0 Returns TRUE if A's n-D bounding box intersects B's n-D bounding box.
- **<#>** - Availability: 2.0.0 -- KNN only available for PostgreSQL 9.1+ Returns the 2D distance between A and B bounding boxes.
- **<->** - Availability: 2.0.0 -- Weak KNN provides nearest neighbors based on geometry centroid distances instead of true distances. Exact results for points, inexact for all other types. Available for PostgreSQL 9.1+ Returns the 2D distance between A and B.
- **AddEdge** - Availability: 2.0.0 requires GEOS >= 3.3.0. Adds a linestring edge to the edge table and associated start and end points to the point nodes table of the specified topology schema using the specified linestring geometry and returns the edgeid of the new (or existing) edge.
- **AddFace** - Availability: 2.0.0 Registers a face primitive to a topology and gets its identifier.
- **AddNode** - Availability: 2.0.0 Adds a point node to the node table in the specified topology schema and returns the nodeid of new node. If point already exists as node, the existing nodeid is returned.
- **AddOverviewConstraints** - Availability: 2.0.0 Tag a raster column as being an overview of another.

- **AddRasterConstraints** - Availability: 2.0.0 Adds raster constraints to a loaded raster table for a specific column that constrains spatial ref, scaling, blocksize, alignment, bands, band type and a flag to denote if raster column is regularly blocked. The table must be loaded with data for the constraints to be inferred. Returns true if the constraint setting was accomplished and if issues a notice.
  - **AsGML** - Availability: 2.0.0 Returns the GML representation of a topogeometry.
  - **CopyTopology** - Availability: 2.0.0 Makes a copy of a topology structure (nodes, edges, faces, layers and TopoGeometries).
  - **DropOverviewConstraints** - Availability: 2.0.0 Untag a raster column from being an overview of another.
  - **DropRasterConstraints** - Availability: 2.0.0 Drops PostGIS raster constraints that refer to a raster table column. Useful if you need to reload data or update your raster column data.
  - **Drop\_Indexes\_Generate\_Script** - Availability: 2.0.0 Generates a script that drops all non-primary key and non-unique indexes on tiger schema and user specified schema. Defaults schema to tiger\_data if no schema is specified.
  - **Drop\_State\_Tables\_Generate\_Script** - Availability: 2.0.0 Generates a script that drops all tables in the specified schema that are prefixed with the state abbreviation. Defaults schema to tiger\_data if no schema is specified.
  - **Geocode\_Intersection** - Availability: 2.0.0 Takes in 2 streets that intersect and a state, city, zip, and outputs a set of possible locations on the first cross street that is at the intersection, also includes a geomout as the point location in NAD 83 long lat, a normalized\_address (addy) for each location, and the rating. The lower the rating the more likely the match. Results are sorted by lowest rating first. Can optionally pass in maximum results, defaults to 10. Uses Tiger data (edges, faces, addr), PostgreSQL fuzzy string matching (soundex, levenshtein).
  - **GetEdgeByPoint** - Availability: 2.0.0 - requires GEOS >= 3.3.0. Find the edge-id of an edge that intersects a given point
  - **GetFaceByPoint** - Availability: 2.0.0 - requires GEOS >= 3.3.0. Find the face-id of a face that intersects a given point
  - **GetNodeByPoint** - Availability: 2.0.0 - requires GEOS >= 3.3.0. Find the id of a node at a point location
  - **GetNodeEdges** - Availability: 2.0 Returns an ordered set of edges incident to the given node.
  - **GetRingEdges** - Availability: 2.0.0 Returns the ordered set of signed edge identifiers met by walking on a given edge side.
  - **GetTopoGeomElements** - Availability: 2.0.0 Returns a set of topoelement objects containing the topological element\_id, element\_type of the given TopoGeometry (primitive elements)
  - **GetTopologySRID** - Availability: 2.0.0 Returns the SRID of a topology in the topology.topology table given the name of the topology.
  - **Get\_Tract** - Availability: 2.0.0 Returns census tract or field from tract table of where the geometry is located. Default to returning short name of tract.
  - **Install\_Missing\_Indexes** - Availability: 2.0.0 Finds all tables with key columns used in geocoder joins and filter conditions that are missing used indexes on those columns and will add them.
  - **Loader\_Generate\_Census\_Script** - Availability: 2.0.0 Generates a shell script for the specified platform for the specified states that will download Tiger census state tract, bg, and tabblocks data tables, stage and load into tiger\_data schema. Each state script is returned as a separate record.
  - **Loader\_Generate\_Script** - Availability: 2.0.0 to support Tiger 2010 structured data and load census tract (tract), block groups (bg), and blocks (tabblocks) tables. Generates a shell script for the specified platform for the specified states that will download Tiger data, stage and load into tiger\_data schema. Each state script is returned as a separate record. Latest version supports Tiger 2010 structural changes and also loads census tract, block groups, and blocks tables.
  - **Missing\_Indexes\_Generate\_Script** - Availability: 2.0.0 Finds all tables with key columns used in geocoder joins that are missing indexes on those columns and will output the SQL DDL to define the index for those tables.
  - **Polygonize** - Availability: 2.0.0 Find and register all faces defined by topology edges
  - **Reverse\_Geocode** - Availability: 2.0.0 Takes a geometry point in a known spatial ref sys and returns a record containing an array of theoretically possible addresses and an array of cross streets. If include\_strnum\_range = true, includes the street range in the cross streets.
-

- **ST\_3DClosestPoint** - Availability: 2.0.0 Returns the 3-dimensional point on g1 that is closest to g2. This is the first point of the 3D shortest line.
  - **ST\_3DDFullyWithin** - Availability: 2.0.0 Returns true if all of the 3D geometries are within the specified distance of one another.
  - **ST\_3DDWithin** - Availability: 2.0.0 For 3d (z) geometry type Returns true if two geometries 3d distance is within number of units.
  - **ST\_3DDistance** - Availability: 2.0.0 For geometry type Returns the 3-dimensional cartesian minimum distance (based on spatial ref) between two geometries in projected units.
  - **ST\_3DIntersects** - Availability: 2.0.0 Returns TRUE if the Geometries "spatially intersect" in 3d - only for points, linestrings, polygons, polyhedral surface (area). With SFCGAL backend enabled also supports TINS
  - **ST\_3DLongestLine** - Availability: 2.0.0 Returns the 3-dimensional longest line between two geometries
  - **ST\_3DMaxDistance** - Availability: 2.0.0 For geometry type Returns the 3-dimensional cartesian maximum distance (based on spatial ref) between two geometries in projected units.
  - **ST\_3DShortestLine** - Availability: 2.0.0 Returns the 3-dimensional shortest line between two geometries
  - **ST\_AddEdgeModFace** - Availability: 2.0 Add a new edge and, if in doing so it splits a face, modify the original face and add a new face.
  - **ST\_AddEdgeNewFaces** - Availability: 2.0 Add a new edge and, if in doing so it splits a face, delete the original face and replace it with two new faces.
  - **ST\_AsGDALRaster** - Availability: 2.0.0 - requires GDAL >= 1.6.0. Return the raster tile in the designated GDAL Raster format. Raster formats are one of those supported by your compiled library. Use ST\_GDALRasters() to get a list of formats supported by your library.
  - **ST\_AsJPEG** - Availability: 2.0.0 - requires GDAL >= 1.6.0. Return the raster tile selected bands as a single Joint Photographic Exports Group (JPEG) image (byte array). If no band is specified and 1 or more than 3 bands, then only the first band is used. If only 3 bands then all 3 bands are used and mapped to RGB.
  - **ST\_AsLatLonText** - Availability: 2.0 Return the Degrees, Minutes, Seconds representation of the given point.
  - **ST\_AsPNG** - Availability: 2.0.0 - requires GDAL >= 1.6.0. Return the raster tile selected bands as a single portable network graphics (PNG) image (byte array). If 1, 3, or 4 bands in raster and no bands are specified, then all bands are used. If more 2 or more than 4 bands and no bands specified, then only band 1 is used. Bands are mapped to RGB or RGBA space.
  - **ST\_AsRaster** - Availability: 2.0.0 - requires GDAL >= 1.6.0. Converts a PostGIS geometry to a PostGIS raster.
  - **ST\_AsTIFF** - Availability: 2.0.0 - requires GDAL >= 1.6.0. Return the raster selected bands as a single TIFF image (byte array). If no band is specified, then will try to use all bands.
  - **ST\_AsX3D** - Availability: 2.0.0: ISO-IEC-19776-1.2-X3DEncodings-XML Returns a Geometry in X3D xml node element format: ISO-IEC-19776-1.2-X3DEncodings-XML
  - **ST\_Aspect** - Availability: 2.0.0 Returns the aspect (in degrees by default) of an elevation raster band. Useful for analyzing terrain.
  - **ST\_Band** - Availability: 2.0.0 Returns one or more bands of an existing raster as a new raster. Useful for building new rasters from existing rasters.
  - **ST\_BandIsNoData** - Availability: 2.0.0 Returns true if the band is filled with only nodata values.
  - **ST\_Clip** - Availability: 2.0.0 Returns the raster clipped by the input geometry. If band number not is specified, all bands are processed. If crop is not specified or TRUE, the output raster is cropped.
  - **ST\_CollectionHomogenize** - Availability: 2.0.0 Given a geometry collection, return the "simplest" representation of the contents.
-

- **ST\_ConcaveHull** - Availability: 2.0.0 The concave hull of a geometry represents a possibly concave geometry that encloses all geometries within the set. You can think of it as shrink wrapping.
  - **ST\_Count** - Availability: 2.0.0 Returns the number of pixels in a given band of a raster or raster coverage. If no band is specified defaults to band 1. If `exclude_nodata_value` is set to true, will only count pixels that are not equal to the nodata value.
  - **ST\_CreateTopoGeo** - Availability: 2.0 Adds a collection of geometries to a given empty topology and returns a message detailing success.
  - **ST\_Distinct4ma** - Availability: 2.0.0 Raster processing function that calculates the number of unique pixel values in a neighborhood.
  - **ST\_FlipCoordinates** - Availability: 2.0.0 Returns a version of the given geometry with X and Y axis flipped. Useful for people who have built latitude/longitude features and need to fix them.
  - **ST\_GDALDrivers** - Availability: 2.0.0 - requires GDAL >= 1.6.0. Returns a list of raster formats supported by your lib gdal. These are the formats you can output your raster using `ST_AsGDALRaster`.
  - **ST\_GeomFromGeoJSON** - Availability: 2.0.0 requires - JSON-C >= 0.9 Takes as input a geojson representation of a geometry and outputs a PostGIS geometry object
  - **ST\_GetFaceEdges** - Availability: 2.0 Returns a set of ordered edges that bound a face.
  - **ST\_HasNoBand** - Availability: 2.0.0 Returns true if there is no band with given band number. If no band number is specified, then band number 1 is assumed.
  - **ST\_HillShade** - Availability: 2.0.0 Returns the hypothetical illumination of an elevation raster band using provided azimuth, altitude, brightness and scale inputs.
  - **ST\_Histogram** - Availability: 2.0.0 Returns a set of record summarizing a raster or raster coverage data distribution separate bin ranges. Number of bins are autocomputed if not specified.
  - **ST\_InterpolatePoint** - Availability: 2.0.0 Return the value of the measure dimension of a geometry at the point closed to the provided point.
  - **ST\_IsEmpty** - Availability: 2.0.0 Returns true if the raster is empty (width = 0 and height = 0). Otherwise, returns false.
  - **ST\_IsValidDetail** - Availability: 2.0.0 - requires GEOS >= 3.3.0. Returns a `valid_detail` (valid,reason,location) row stating if a geometry is valid or not and if not valid, a reason why and a location where.
  - **ST\_IsValidReason** - Availability: 2.0 - requires GEOS >= 3.3.0 for the version taking flags. Returns text stating if a geometry is valid or not and if not valid, a reason why.
  - **ST\_MakeLine** - Availability: 2.0.0 - Support for linestring input elements was introduced Creates a Linestring from point, multipoint, or line geometries.
  - **ST\_MakeValid** - Availability: 2.0.0, requires GEOS-3.3.0 Attempts to make an invalid geometry valid without losing vertices.
  - **ST\_MapAlgebraExpr** - Availability: 2.0.0 1 raster band version: Creates a new one band raster formed by applying a valid PostgreSQL algebraic operation on the input raster band and of pixeltype provided. Band 1 is assumed if no band is specified.
  - **ST\_MapAlgebraExpr** - Availability: 2.0.0 2 raster band version: Creates a new one band raster formed by applying a valid PostgreSQL algebraic operation on the two input raster bands and of pixeltype provided. band 1 of each raster is assumed if no band numbers are specified. The resulting raster will be aligned (scale, skew and pixel corners) on the grid defined by the first raster and have its extent defined by the "extenttype" parameter. Values for "extenttype" can be: INTERSECTION, UNION, FIRST, SECOND.
  - **ST\_MapAlgebraFct** - Availability: 2.0.0 1 band version - Creates a new one band raster formed by applying a valid PostgreSQL function on the input raster band and of pixeltype provided. Band 1 is assumed if no band is specified.
  - **ST\_MapAlgebraFct** - Availability: 2.0.0 2 band version - Creates a new one band raster formed by applying a valid PostgreSQL function on the 2 input raster bands and of pixeltype provided. Band 1 is assumed if no band is specified. Extent type defaults to INTERSECTION if not specified.
-

- **ST\_MapAlgebraFctNgb** - Availability: 2.0.0 1-band version: Map Algebra Nearest Neighbor using user-defined PostgreSQL function. Return a raster which values are the result of a PLPGSQL user function involving a neighborhood of values from the input raster band.
  - **ST\_Max4ma** - Availability: 2.0.0 Raster processing function that calculates the maximum pixel value in a neighborhood.
  - **ST\_Mean4ma** - Availability: 2.0.0 Raster processing function that calculates the mean pixel value in a neighborhood.
  - **ST\_Min4ma** - Availability: 2.0.0 Raster processing function that calculates the minimum pixel value in a neighborhood.
  - **ST\_ModEdgeHeal** - Availability: 2.0 Heal two edges by deleting the node connecting them, modifying the first edge and deleting the second edge. Returns the id of the deleted node.
  - **ST\_NewEdgeHeal** - Availability: 2.0 Heal two edges by deleting the node connecting them, deleting both edges, and replacing them with an edge whose direction is the same as the first edge provided.
  - **ST\_Node** - Availability: 2.0.0 - requires GEOS >= 3.3.0. Node a set of linestrings.
  - **ST\_NumPatches** - Availability: 2.0.0 Return the number of faces on a Polyhedral Surface. Will return null for non-polyhedral geometries.
  - **ST\_OffsetCurve** - Availability: 2.0 - requires GEOS >= 3.2, improved with GEOS >= 3.3 Return an offset line at a given distance and side from an input line. Useful for computing parallel lines about a center line
  - **ST\_PatchN** - Availability: 2.0.0 Return the 1-based Nth geometry (face) if the geometry is a POLYHEDRALSURFACE, POLYHEDRALSURFACEM. Otherwise, return NULL.
  - **ST\_PixelAsPolygon** - Availability: 2.0.0 Returns the polygon geometry that bounds the pixel for a particular row and column.
  - **ST\_PixelAsPolygons** - Availability: 2.0.0 Returns the polygon geometry that bounds every pixel of a raster band along with the value, the X and the Y raster coordinates of each pixel.
  - **ST\_Project** - Availability: 2.0.0 Returns a POINT projected from a start point using a distance in meters and bearing (azimuth) in radians.
  - **ST\_Quantile** - Availability: 2.0.0 Compute quantiles for a raster or raster table coverage in the context of the sample or population. Thus, a value could be examined to be at the raster's 25%, 50%, 75% percentile.
  - **ST\_Range4ma** - Availability: 2.0.0 Raster processing function that calculates the range of pixel values in a neighborhood.
  - **ST\_Reclass** - Availability: 2.0.0 Creates a new raster composed of band types reclassified from original. The nband is the band to be changed. If nband is not specified assumed to be 1. All other bands are returned unchanged. Use case: convert a 16BUI band to a 8BUI and so forth for simpler rendering as viewable formats.
  - **ST\_RelateMatch** - Availability: 2.0.0 - requires GEOS >= 3.3.0. Returns true if intersectionMatrixPattern1 implies intersectionMatrixPattern2
  - **ST\_RemEdgeModFace** - Availability: 2.0 Removes an edge and, if the removed edge separated two faces, delete one of the them and modify the other to take the space of both.
  - **ST\_RemEdgeNewFace** - Availability: 2.0 Removes an edge and, if the removed edge separated two faces, delete the original faces and replace them with a new face.
  - **ST\_Resample** - Availability: 2.0.0 Requires GDAL 1.6.1+ Resample a raster using a specified resampling algorithm, new dimensions, an arbitrary grid corner and a set of raster georeferencing attributes defined or borrowed from another raster.
  - **ST\_Rescale** - Availability: 2.0.0 Requires GDAL 1.6.1+ Resample a raster by adjusting only its scale (or pixel size). New pixel values are computed using the NearestNeighbor (english or american spelling), Bilinear, Cubic, CubicSpline or Lanczos resampling algorithm. Default is NearestNeighbor.
  - **ST\_Reskew** - Availability: 2.0.0 Requires GDAL 1.6.1+ Resample a raster by adjusting only its skew (or rotation parameters). New pixel values are computed using the NearestNeighbor (english or american spelling), Bilinear, Cubic, CubicSpline or Lanczos resampling algorithm. Default is NearestNeighbor.
-

- **ST\_SameAlignment** - Availability: 2.0.0 Returns true if rasters have same skew, scale, spatial ref, and offset (pixels can be put on same grid without cutting into pixels) and false if they don't with notice detailing issue.
- **ST\_SetBandIsNoData** - Availability: 2.0.0 Sets the isnodata flag of the band to TRUE.
- **ST\_SharedPaths** - Availability: 2.0.0 requires GEOS >= 3.3.0. Returns a collection containing paths shared by the two input linestrings/multilinestrings.
- **ST\_Slope** - Availability: 2.0.0 Returns the slope (in degrees by default) of an elevation raster band. Useful for analyzing terrain.
- **ST\_Snap** - Availability: 2.0.0 requires GEOS >= 3.3.0. Snap segments and vertices of input geometry to vertices of a reference geometry.
- **ST\_SnapToGrid** - Availability: 2.0.0 Requires GDAL 1.6.1+ Resample a raster by snapping it to a grid. New pixel values are computed using the NearestNeighbor (english or american spelling), Bilinear, Cubic, CubicSpline or Lanczos resampling algorithm. Default is NearestNeighbor.
- **ST\_Split** - Availability: 2.0.0 Returns a collection of geometries resulting by splitting a geometry.
- **ST\_StdDev4ma** - Availability: 2.0.0 Raster processing function that calculates the standard deviation of pixel values in a neighborhood.
- **ST\_Sum4ma** - Availability: 2.0.0 Raster processing function that calculates the sum of all pixel values in a neighborhood.
- **ST\_SummaryStats** - Availability: 2.0.0 Returns summarystats consisting of count, sum, mean, stddev, min, max for a given raster band of a raster or raster coverage. Band 1 is assumed is no band is specified.
- **ST\_Transform** - Availability: 2.0.0 Requires GDAL 1.6.1+ Reprojects a raster in a known spatial reference system to another known spatial reference system using specified resampling algorithm. Options are NearestNeighbor, Bilinear, Cubic, CubicSpline, Lanczos defaulting to NearestNeighbor.
- **ST\_UnaryUnion** - Availability: 2.0.0 - requires GEOS >= 3.3.0. Like ST\_Union, but working at the geometry component level.
- **ST\_Union** - Availability: 2.0.0 Returns the union of a set of raster tiles into a single raster composed of 1 or more bands.
- **ST\_ValueCount** - Availability: 2.0.0 Returns a set of records containing a pixel band value and count of the number of pixels in a given band of a raster (or a raster coverage) that have a given set of values. If no band is specified defaults to band 1. By default nodata value pixels are not counted. and all other values in the pixel are output and pixel band values are rounded to the nearest integer.
- **TopoElementArray\_Agg** - Availability: 2.0.0 Returns a topoelementarray for a set of element\_id, type arrays (topoelements)
- **TopoGeo\_AddLineString** - Availability: 2.0.0 Adds a linestring to an existing topology using a tolerance and possibly splitting existing edges/faces. Returns edge identifiers
- **TopoGeo\_AddPoint** - Availability: 2.0.0 Adds a point to an existing topology using a tolerance and possibly splitting an existing edge.
- **TopoGeo\_AddPolygon** - Availability: 2.0.0 Adds a polygon to an existing topology using a tolerance and possibly splitting existing edges/faces.
- **TopologySummary** - Availability: 2.0.0 Takes a topology name and provides summary totals of types of objects in topology
- **Topology\_Load\_Tiger** - Availability: 2.0.0 Loads a defined region of tiger data into a PostGIS Topology and transforming the tiger data to spatial reference of the topology and snapping to the precision tolerance of the topology.
- **toTopoGeom** - Availability: 2.0 Converts a simple Geometry into a topo geometry
- **~=** - Availability: 2.0.0 Returns TRUE if A's bounding box is the same as B's.

The functions given below are PostGIS functions that are enhanced in PostGIS 2.0.

- **AddGeometryColumn** - Enhanced: 2.0.0 use\_typmod argument introduced. Defaults to creating typmod geometry column instead of constraint-based.
  - **Box2D** - Enhanced: 2.0.0 support for Polyhedral surfaces, Triangles and TIN was introduced.
  - **Box3D** - Enhanced: 2.0.0 support for Polyhedral surfaces, Triangles and TIN was introduced.
  - **Geocode** - Enhanced: 2.0.0 to support Tiger 2010 structured data and revised some logic to improve speed, accuracy of geocoding, and to offset point from centerline to side of street address is located on. The new parameter max\_results useful for specifying number of best results or just returning the best result.
  - **GeometryType** - Enhanced: 2.0.0 support for Polyhedral surfaces, Triangles and TIN was introduced.
  - **Populate\_Geometry\_Columns** - Enhanced: 2.0.0 use\_typmod optional argument was introduced that allows controlling if columns are created with typmodifiers or with check constraints.
  - **ST\_Intersection** - Enhanced: 2.0.0 - Intersection in the raster space was introduced. In earlier pre-2.0.0 versions, only intersection performed in vector space were supported.
  - **ST\_Intersects** - Enhanced: 2.0.0 support raster/raster intersects was introduced.
  - **ST\_Value** - Enhanced: 2.0.0 exclude\_nodata\_value optional argument was added.
  - **ST\_3DExtent** - Enhanced: 2.0.0 support for Polyhedral surfaces, Triangles and TIN was introduced.
  - **ST\_Accum** - Enhanced: 2.0.0 support for Polyhedral surfaces, Triangles and TIN was introduced.
  - **ST\_Affine** - Enhanced: 2.0.0 support for Polyhedral surfaces, Triangles and TIN was introduced.
  - **ST\_Area** - Enhanced: 2.0.0 - support for 2D polyhedral surfaces was introduced.
  - **ST\_AsBinary** - Enhanced: 2.0.0 support for Polyhedral surfaces, Triangles and TIN was introduced.
  - **ST\_AsBinary** - Enhanced: 2.0.0 support for higher coordinate dimensions was introduced.
  - **ST\_AsBinary** - Enhanced: 2.0.0 support for specifying endian with geography was introduced.
  - **ST\_AsEWKB** - Enhanced: 2.0.0 support for Polyhedral surfaces, Triangles and TIN was introduced.
  - **ST\_AsEWKT** - Enhanced: 2.0.0 support for Geography, Polyhedral surfaces, Triangles and TIN was introduced.
  - **ST\_AsGML** - Enhanced: 2.0.0 prefix support was introduced. Option 4 for GML3 was introduced to allow using LineString instead of Curve tag for lines. GML3 Support for Polyhedral surfaces and TINs was introduced. Option 32 was introduced to output the box.
  - **ST\_AsKML** - Enhanced: 2.0.0 - Add prefix namespace. Default is no prefix
  - **ST\_Azimuth** - Enhanced: 2.0.0 support for geography was introduced.
  - **ST\_ChangeEdgeGeom** - Enhanced: 2.0.0 adds topological consistency enforcement
  - **ST\_Dimension** - Enhanced: 2.0.0 support for Polyhedral surfaces and TINs was introduced. No longer throws an exception if given empty geometry.
  - **ST\_Dump** - Enhanced: 2.0.0 support for Polyhedral surfaces, Triangles and TIN was introduced.
  - **ST\_DumpPoints** - Enhanced: 2.0.0 support for Polyhedral surfaces, Triangles and TIN was introduced.
  - **ST\_Expand** - Enhanced: 2.0.0 support for Polyhedral surfaces, Triangles and TIN was introduced.
  - **ST\_Extent** - Enhanced: 2.0.0 support for Polyhedral surfaces, Triangles and TIN was introduced.
  - **ST\_Force2D** - Enhanced: 2.0.0 support for Polyhedral surfaces was introduced.
  - **ST\_ForceRHR** - Enhanced: 2.0.0 support for Polyhedral surfaces was introduced.
  - **ST\_Force3D** - Enhanced: 2.0.0 support for Polyhedral surfaces was introduced.
-

- **ST\_Force3DZ** - Enhanced: 2.0.0 support for Polyhedral surfaces was introduced.
  - **ST\_ForceCollection** - Enhanced: 2.0.0 support for Polyhedral surfaces was introduced.
  - **ST\_GMLToSQL** - Enhanced: 2.0.0 support for Polyhedral surfaces and TIN was introduced.
  - **ST\_GMLToSQL** - Enhanced: 2.0.0 default srid optional parameter added.
  - **ST\_GeomFromEWKB** - Enhanced: 2.0.0 support for Polyhedral surfaces and TIN was introduced.
  - **ST\_GeomFromEWKT** - Enhanced: 2.0.0 support for Polyhedral surfaces and TIN was introduced.
  - **ST\_GeomFromGML** - Enhanced: 2.0.0 support for Polyhedral surfaces and TIN was introduced.
  - **ST\_GeomFromGML** - Enhanced: 2.0.0 default srid optional parameter added.
  - **ST\_GeometryN** - Enhanced: 2.0.0 support for Polyhedral surfaces, Triangles and TIN was introduced.
  - **ST\_GeometryType** - Enhanced: 2.0.0 support for Polyhedral surfaces was introduced.
  - **ST\_IsClosed** - Enhanced: 2.0.0 support for Polyhedral surfaces was introduced.
  - **ST\_MakeEnvelope** - Enhanced: 2.0: Ability to specify an envelope without specifying an SRID was introduced.
  - **ST\_MakeValid** - Enhanced: 2.0.1, speed improvements requires GEOS-3.3.4
  - **ST\_NPoints** - Enhanced: 2.0.0 support for Polyhedral surfaces was introduced.
  - **ST\_NumGeometries** - Enhanced: 2.0.0 support for Polyhedral surfaces, Triangles and TIN was introduced.
  - **ST\_Relate** - Enhanced: 2.0.0 - added support for specifying boundary node rule (requires GEOS >= 3.0).
  - **ST\_Rotate** - Enhanced: 2.0.0 support for Polyhedral surfaces, Triangles and TIN was introduced.
  - **ST\_Rotate** - Enhanced: 2.0.0 additional parameters for specifying the origin of rotation were added.
  - **ST\_RotateX** - Enhanced: 2.0.0 support for Polyhedral surfaces, Triangles and TIN was introduced.
  - **ST\_RotateY** - Enhanced: 2.0.0 support for Polyhedral surfaces, Triangles and TIN was introduced.
  - **ST\_RotateZ** - Enhanced: 2.0.0 support for Polyhedral surfaces, Triangles and TIN was introduced.
  - **ST\_Scale** - Enhanced: 2.0.0 support for Polyhedral surfaces, Triangles and TIN was introduced.
  - **ST\_ShiftLongitude** - Enhanced: 2.0.0 support for Polyhedral surfaces and TIN was introduced.
  - **ST\_Summary** - Enhanced: 2.0.0 added support for geography
  - **ST\_Transform** - Enhanced: 2.0.0 support for Polyhedral surfaces was introduced.
  - **ValidateTopology** - Enhanced: 2.0.0 more efficient edge crossing detection and fixes for false positives that were existent in prior versions.
  - **&&** - Enhanced: 2.0.0 support for Polyhedral surfaces was introduced.
-

## 14.12.7 PostGIS Functions changed behavior in 2.0

The functions given below are PostGIS functions that have changed behavior in PostGIS 2.0 and may require application changes.

### Note

Most deprecated functions have been removed. These are functions that haven't been documented since 1.2 or some internal functions that were never documented. If you are using a function that you don't see documented, it's probably deprecated, about to be deprecated, or internal and should be avoided. If you have applications or tools that rely on deprecated functions, please refer to [?qandaentry] for more details.

### Note

Bounding boxes of geometries have been changed from float4 to double precision (float8). This has an impact on answers you get using bounding box operators and casting of bounding boxes to geometries. E.g ST\_SetSRID(abbox) will often return a different more accurate answer in PostGIS 2.0+ than it did in prior versions which may very well slightly change answers to view port queries.

### Note

The arguments hasnodata was replaced with exclude\_nodata\_value which has the same meaning as the older hasnodata but clearer in purpose.

- **AddGeometryColumn** - Changed: 2.0.0 This function no longer updates geometry\_columns since geometry\_columns is a view that reads from system catalogs. It by default also does not create constraints, but instead uses the built in type modifier behavior of PostgreSQL. So for example building a wgs84 POINT column with this function is now equivalent to: ALTER TABLE some\_table ADD COLUMN geom geometry(Point,4326);
- **AddGeometryColumn** - Changed: 2.0.0 If you require the old behavior of constraints use the default use\_typmod, but set it to false.
- **AddGeometryColumn** - Changed: 2.0.0 Views can no longer be manually registered in geometry\_columns, however views built against geometry typmod tables geometries and used without wrapper functions will register themselves correctly because they inherit the typmod behavior of their parent table column. Views that use geometry functions that output other geometries will need to be cast to typmod geometries for these view geometry columns to be registered correctly in geometry\_columns. Refer to .
- **DropGeometryColumn** - Changed: 2.0.0 This function is provided for backward compatibility. Now that since geometry\_columns is now a view against the system catalogs, you can drop a geometry column like any other table column using ALTER TABLE
- **DropGeometryTable** - Changed: 2.0.0 This function is provided for backward compatibility. Now that since geometry\_columns is now a view against the system catalogs, you can drop a table with geometry columns like any other table using DROP TABLE
- **Populate\_Geometry\_Columns** - Changed: 2.0.0 By default, now uses type modifiers instead of check constraints to constrain geometry types. You can still use check constraint behavior instead by using the new use\_typmod and setting it to false.
- **Box3D** - Changed: 2.0.0 In pre-2.0 versions, there used to be a box2d instead of box3d. Since box2d is a deprecated type, this was changed to box3d.
- **ST\_GDALDrivers** - Changed: 2.0.6, 2.1.3 - by default no drivers are enabled, unless GUC or Environment variable gdal\_enabled\_driver is set.
- **ST\_ScaleX** - Changed: 2.0.0. In WKTRaster versions this was called ST\_PixelSizeX.
- **ST\_ScaleY** - Changed: 2.0.0. In WKTRaster versions this was called ST\_PixelSizeY.
- **ST\_SetScale** - Changed: 2.0.0 In WKTRaster versions this was called ST\_SetPixelSize. This was changed in 2.0.0.

- **ST\_3DExtent** - Changed: 2.0.0 In prior versions this used to be called ST\_Extent3D
- **ST\_3DLength** - Changed: 2.0.0 In prior versions this used to be called ST\_Length3D
- **ST\_3DMakeBox** - Changed: 2.0.0 In prior versions this used to be called ST\_MakeBox3D
- **ST\_3DPerimeter** - Changed: 2.0.0 In prior versions this used to be called ST\_Perimeter3D
- **ST\_AsBinary** - Changed: 2.0.0 Inputs to this function can not be unknown -- must be geometry. Constructs such as ST\_AsBinary('POINT(1 2)') are no longer valid and you will get an error: st\_asbinary(unknown) is not unique error. Code like that needs to be changed to ST\_AsBinary('POINT(1 2)::geometry');. If that is not possible, then install legacy.sql.
- **ST\_AsGML** - Changed: 2.0.0 use default named args
- **ST\_AsGeoJSON** - Changed: 2.0.0 support default args and named args.
- **ST\_AsKML** - Changed: 2.0.0 - uses default args and supports named args
- **ST\_AsSVG** - Changed: 2.0.0 to use default args and support named args
- **ST\_EndPoint** - Changed: 2.0.0 no longer works with single geometry multilinestrings. In older versions of PostGIS -- a single line multilinestring would work happily with this function and return the start point. In 2.0.0 it just returns NULL like any other multilinestring. The older behavior was an undocumented feature, but people who assumed they had their data stored as LINESRING may experience these returning NULL in 2.0 now.
- **ST\_GeomFromText** - Changed: 2.0.0 In prior versions of PostGIS ST\_GeomFromText('GEOMETRYCOLLECTION(EMPTY)') was allowed. This is now illegal in PostGIS 2.0.0 to better conform with SQL/MM standards. This should now be written as ST\_GeomFromText('GEOMETRYCOLLECTION EMPTY')
- **ST\_GeometryN** - Changed: 2.0.0 Prior versions would return NULL for singular geometries. This was changed to return the geometry for ST\_GeometryN(...,1) case.
- **ST\_IsEmpty** - Changed: 2.0.0 In prior versions of PostGIS ST\_GeomFromText('GEOMETRYCOLLECTION(EMPTY)') was allowed. This is now illegal in PostGIS 2.0.0 to better conform with SQL/MM standards
- **ST\_Length** - Changed: 2.0.0 Breaking change -- in prior versions applying this to a MULTI/POLYGON of type geography would give you the perimeter of the POLYGON/MULTIPOLYGON. In 2.0.0 this was changed to return 0 to be in line with geometry behavior. Please use ST\_Perimeter if you want the perimeter of a polygon
- **ST\_LocateAlong** - Changed: 2.0.0 in prior versions this used to be called ST\_Locate\_Along\_Measure. The old name has been deprecated and will be removed in the future but is still available.
- **ST\_LocateBetween** - Changed: 2.0.0 - in prior versions this used to be called ST\_Locate\_Between\_Measures. The old name has been deprecated and will be removed in the future but is still available for backward compatibility.
- **ST\_ModEdgeSplit** - Changed: 2.0 - In prior versions, this was misnamed ST\_ModEdgesSplit
- **ST\_NumGeometries** - Changed: 2.0.0 In prior versions this would return NULL if the geometry was not a collection/MULTI type. 2.0.0+ now returns 1 for single geometries e.g POLYGON, LINESRING, POINT.
- **ST\_NumInteriorRings** - Changed: 2.0.0 - in prior versions it would allow passing a MULTIPOLYGON, returning the number of interior rings of first POLYGON.
- **ST\_PointN** - Changed: 2.0.0 no longer works with single geometry multilinestrings. In older versions of PostGIS -- a single line multilinestring would work happily with this function and return the start point. In 2.0.0 it just returns NULL like any other multilinestring.
- **ST\_StartPoint** - Changed: 2.0.0 no longer works with single geometry multilinestrings. In older versions of PostGIS -- a single line multilinestring would work happily with this function and return the start point. In 2.0.0 it just returns NULL like any other multilinestring. The older behavior was an undocumented feature, but people who assumed they had their data stored as LINESRING may experience these returning NULL in 2.0 now.

## 14.12.8 PostGIS Functions new, behavior changed, or enhanced in 1.5

The functions given below are PostGIS functions that were introduced or enhanced in this minor release.

- **PostGIS\_LibXML\_Version** - Availability: 1.5 Returns the version number of the libxml2 library.
  - **ST\_AddMeasure** - Availability: 1.5.0 Return a derived geometry with measure elements linearly interpolated between the start and end points.
  - **ST\_AsBinary** - Availability: 1.5.0 geography support was introduced. Return the Well-Known Binary (WKB) representation of the geometry/geography without SRID meta data.
  - **ST\_AsGML** - Availability: 1.5.0 geography support was introduced. Return the geometry as a GML version 2 or 3 element.
  - **ST\_AsGeoJSON** - Availability: 1.5.0 geography support was introduced. Return the geometry as a GeoJSON element.
  - **ST\_AsText** - Availability: 1.5 - support for geography was introduced. Return the Well-Known Text (WKT) representation of the geometry/geography without SRID metadata.
  - **ST\_Buffer** - Availability: 1.5 - **ST\_Buffer** was enhanced to support different endcaps and join types. These are useful for example to convert road linestrings into polygon roads with flat or square edges instead of rounded edges. Thin wrapper for geography was added. - requires GEOS >= 3.2 to take advantage of advanced geometry functionality. (T)Returns a geometry covering all points within a given distance from the input geometry.
  - **ST\_ClosestPoint** - Availability: 1.5.0 Returns the 2-dimensional point on g1 that is closest to g2. This is the first point of the shortest line.
  - **ST\_CollectionExtract** - Availability: 1.5.0 Given a (multi)geometry, return a (multi)geometry consisting only of elements of the specified type.
  - **ST\_Covers** - Availability: 1.5 - support for geography was introduced. Returns 1 (TRUE) if no point in Geometry B is outside Geometry A
  - **ST\_DFullyWithin** - Availability: 1.5.0 Returns true if all of the geometries are within the specified distance of one another
  - **ST\_DWithin** - Availability: 1.5.0 support for geography was introduced Returns true if the geometries are within the specified distance of one another. For geometry units are in those of spatial reference and For geography units are in meters and measurement is defaulted to use\_spheroid=true (measure around spheroid), for faster check, use\_spheroid=false to measure along sphere.
  - **ST\_Distance** - Availability: 1.5.0 geography support was introduced in 1.5. Speed improvements for planar to better handle large or many vertex geometries For geometry type Returns the 2D Cartesian distance between two geometries in projected units (based on spatial ref). For geography type defaults to return minimum geodesic distance between two geographies in meters.
  - **ST\_DistanceSphere** - Availability: 1.5 - support for other geometry types besides points was introduced. Prior versions only work with points. Returns minimum distance in meters between two lon/lat geometries. Uses a spherical earth and radius derived from the spheroid defined by the SRID. Faster than **ST\_DistanceSpheroid** , but less accurate. PostGIS versions prior to 1.5 only implemented for points.
  - **ST\_DistanceSpheroid** - Availability: 1.5 - support for other geometry types besides points was introduced. Prior versions only work with points. Returns the minimum distance between two lon/lat geometries given a particular spheroid. PostGIS versions prior to 1.5 only support points.
  - **ST\_DumpPoints** - Availability: 1.5.0 Returns a set of geometry\_dump (geom,path) rows of all points that make up a geometry.
  - **ST\_Envelope** - Availability: 1.5.0 behavior changed to output double precision instead of float4 Returns a geometry representing the double precision (float8) bounding box of the supplied geometry.
  - **ST\_GMLToSQL** - Availability: 1.5, requires libxml2 1.6+ Return a specified ST\_Geometry value from GML representation. This is an alias name for **ST\_GeomFromGML**
-

- **ST\_GeomFromGML** - Availability: 1.5, requires libxml2 1.6+ Takes as input GML representation of geometry and outputs a PostGIS geometry object
- **ST\_GeomFromKML** - Availability: 1.5,libxml2 2.6+ Takes as input KML representation of geometry and outputs a PostGIS geometry object
- **~=** - Availability: 1.5.0 changed behavior Returns TRUE if A's bounding box is the same as B's.
- **ST\_HausdorffDistance** - Availability: 1.5.0 - requires GEOS >= 3.2.0 Returns the Hausdorff distance between two geometries. Basically a measure of how similar or dissimilar 2 geometries are. Units are in the units of the spatial reference system of the geometries.
- **ST\_Intersection** - Availability: 1.5 support for geography data type was introduced. (T)Returns a geometry that represents the shared portion of geomA and geomB.
- **ST\_Intersects** - Availability: 1.5 support for geography was introduced. Returns TRUE if the Geometries/Geography "spatially intersect in 2D" - (share any portion of space) and FALSE if they don't (they are Disjoint). For geography -- tolerance is 0.00001 meters (so any points that close are considered to intersect)
- **ST\_Length** - Availability: 1.5.0 geography support was introduced in 1.5. Returns the 2D length of the geometry if it is a LineString or MultiLineString. geometry are in units of spatial reference and geography are in meters (default spheroid)
- **ST\_LongestLine** - Availability: 1.5.0 Returns the 2-dimensional longest line points of two geometries. The function will only return the first longest line if more than one, that the function finds. The line returned will always start in g1 and end in g2. The length of the line this function returns will always be the same as st\_maxdistance returns for g1 and g2.
- **ST\_MakeEnvelope** - Availability: 1.5 Creates a rectangular Polygon formed from the given minimums and maximums. Input values must be in SRS specified by the SRID.
- **ST\_MaxDistance** - Availability: 1.5.0 Returns the 2-dimensional largest distance between two geometries in projected units.
- **ST\_ShortestLine** - Availability: 1.5.0 Returns the 2-dimensional shortest line between two geometries
- **&&** - Availability: 1.5.0 support for geography was introduced. Returns TRUE if A's 2D bounding box intersects B's 2D bounding box.

#### 14.12.9 PostGIS Functions new, behavior changed, or enhanced in 1.4

The functions given below are PostGIS functions that were introduced or enhanced in the 1.4 release.

- **Populate\_Geometry\_Columns** - Ensures geometry columns are defined with type modifiers or have appropriate spatial constraints This ensures they will be registered correctly in geometry\_columns view. By default will convert all geometry columns with no type modifier to ones with type modifiers. To get old behavior set use\_typmod=false Availability: 1.4.0
- **ST\_AsSVG** - Returns a Geometry in SVG path data given a geometry or geography object. Availability: 1.2.2. Availability: 1.4.0 Changed in PostGIS 1.4.0 to include L command in absolute path to conform to <http://www.w3.org/TR/SVG/paths.html#PathData>
- **ST\_Collect** - Return a specified ST\_Geometry value from a collection of other geometries. Availability: 1.4.0 - ST\_Collect(geomarray) was introduced. ST\_Collect was enhanced to handle more geometries faster.
- **ST\_ContainsProperly** - Returns true if B intersects the interior of A but not the boundary (or exterior). A does not contain properly itself, but does contain itself. Availability: 1.4.0 - requires GEOS >= 3.1.0.
- **ST\_Extent** - an aggregate function that returns the bounding box that bounds rows of geometries. Availability: 1.4.0
- **ST\_GeoHash** - Return a GeoHash representation of the geometry. Availability: 1.4.0
- **ST\_IsValidReason** - Returns text stating if a geometry is valid or not and if not valid, a reason why. Availability: 1.4 - requires GEOS >= 3.1.0.
- **ST\_LineCrossingDirection** - Given 2 linestrings, returns a number between -3 and 3 denoting what kind of crossing behavior. 0 is no crossing. Availability: 1.4

- **ST\_LocateBetweenElevations** - Return a derived geometry (collection) value with elements that intersect the specified range of elevations inclusively. Only 3D, 4D LINESTRINGS and MULTILINESTRINGS are supported. Availability: 1.4.0
- **ST\_MakeLine** - Creates a Linestring from point, multipoint, or line geometries. Availability: 1.4.0 - ST\_MakeLine(geomarray) was introduced. ST\_MakeLine aggregate functions was enhanced to handle more points faster.
- **ST\_MinimumBoundingCircle** - Returns the smallest circle polygon that can fully contain a geometry. Default uses 48 segments per quarter circle. Availability: 1.4.0 - requires GEOS
- **ST\_Union** - Returns a geometry that represents the point set union of the Geometries. Availability: 1.4.0 - ST\_Union was enhanced. ST\_Union(geomarray) was introduced and also faster aggregate collection in PostgreSQL. If you are using GEOS 3.1.0+ ST\_Union will use the faster Cascaded Union algorithm described in <http://blog.cleverelephant.ca/2009/01/must-faster-unions-in-postgis-14.html>

#### 14.12.10 PostGIS Functions new in 1.3

The functions given below are PostGIS functions that were introduced in the 1.3 release.

- **ST\_AsGML** - Return the geometry as a GML version 2 or 3 element. Availability: 1.3.2
  - **ST\_AsGeoJSON** - Return the geometry as a GeoJSON element. Availability: 1.3.4
  - **ST\_SimplifyPreserveTopology** - Returns a "simplified" version of the given geometry using the Douglas-Peucker algorithm. Will avoid creating derived geometries (polygons in particular) that are invalid. Availability: 1.3.3
-

## Chapter 15

# Reporting Problems

### 15.1 Reporting Software Bugs

Reporting bugs effectively is a fundamental way to help PostGIS development. The most effective bug report is that enabling PostGIS developers to reproduce it, so it would ideally contain a script triggering it and every information regarding the environment in which it was detected. Good enough info can be extracted running `SELECT postgis_full_version()` [for postgres] and `SELECT version()` [for postgresql].

If you aren't using the latest release, it's worth taking a look at its [release changelog](#) first, to find out if your bug has already been fixed.

Using the [PostGIS bug tracker](#) will ensure your reports are not discarded, and will keep you informed on its handling process. Before reporting a new bug please query the database to see if it is a known one, and if it is please add any new information you have about it.

You might want to read Simon Tatham's paper about [How to Report Bugs Effectively](#) before filing a new report.

### 15.2 Reporting Documentation Issues

The documentation should accurately reflect the features and behavior of the software. If it doesn't, it could be because of a software bug or because the documentation is in error or deficient.

Documentation issues can also be reported to the [PostGIS bug tracker](#).

If your revision is trivial, just describe it in a new bug tracker issue, being specific about its location in the documentation.

If your changes are more extensive, a Subversion patch is definitely preferred. This is a four step process on Unix (assuming you already have [Subversion](#) installed):

1. Check out a copy of PostGIS' Subversion trunk. On Unix, type:

```
svn checkout http://svn.osgeo.org/postgis/trunk/
```

This will be stored in the directory `./trunk`

2. Make your changes to the documentation with your favorite text editor. On Unix, type (for example):

```
vim trunk/doc/postgis.xml
```

Note that the documentation is written in DocBook XML rather than HTML, so if you are not familiar with it please follow the example of the rest of the documentation.

3. Make a patch file containing the differences from the master copy of the documentation. On Unix, type:

```
svn diff trunk/doc/postgis.xml > doc.patch
```

4. Attach the patch to a new issue in bug tracker.

## Appendix A

# Appendix

### A.1 Release 2.3.8

Release date: 2018/11/24

This is a bug fix and performance improvement release.

#### A.1.1 Bug Fixes and Enhancements

#4071, ST\_ClusterKMeans crash on NULL/EMPTY fixed (Darafei Praliaskouski)

#4074, Disable interrupt tests by default (Regina Obe)

#3997, fix bug in lwgeom\_median and avoid division by zero (Raúl Marín)

#4093, Inconsistent results from qsort callback (yugr)

#4160, Use qualified names in topology extension install (Raúl Marín)

#4189, Fix undefined behaviour in SADFWrite (Raúl Marín)

#4191, Fix undefined behaviour in parray\_clone\_deep (Raúl Marín)

#4020, Fix leftovers in topology upgrade from 2.1 (Sandro Santilli)

#4203, Fix build with GNU Make 4.1 (Sandro Santilli)

#4206, Fix support for PostgreSQL 12 dev branch (Laurenz Albe)

#3457, Fix raster envelope shortcut in ST\_Clip (Sai-bot)

#4223, Fix parallel/near rectangle case in geography (Paul Ramsey)

#4326, Allocate enough memory in gidx\_to\_string (Raúl Marín)

#4247, Avoid undefined behaviour in next\_float functions (Raúl Marín)

#4249, Fix undefined behaviour in raster intersection (Raúl Marín)

#4246, Fix undefined behaviour in ST\_3DDistance (Raúl Marín)

#4244, Avoid unaligned memory access in BOX2D\_out (Raúl Marín)

### A.2 Release 2.3.7

Release date: 2018/04/06

This is a bug fix and performance improvement release.

---

## A.2.1 Bug Fixes and Enhancements

#3055, [raster] ST\_Clip() on a raster without band crashes the server (Regina Obe)

#3978, Fix KNN when upgrading from 2.1 or older (Sandro Santilli)

#4003, lwpoly\_construct\_circle: Avoid division by zero (Raúl Marín Rodríguez)

#4017, lwgeom lexer memory corruption (Peter E)

#4020, Casting from box3d to geometry now returns correctly connected PolyhedralSurface (Matthias Bay)

#4025, #4032 Incorrect answers for temporally "almost overlapping" ranges in ST\_ClosestPointOfApproach and ST\_CPAWithin (Paul Ramsey, Darafei Praliaskouski)

#4052, schema qualify several functions in geography (Regina Obe)

## A.3 Release 2.3.6

Release date: 2018/01/17

This is a bug fix and performance improvement release.

### A.3.1 Bug Fixes and Enhancements

#3713, Support encodings that happen to output a ` character

#3822, Have postgis\_full\_version() also show and check version of PostgreSQL the scripts were built against (Sandro Santilli)

#3965, ST\_ClusterKMeans used to lose some clusters on initialization (Darafei Praliaskouski)

#3956, Brin opclass object does not upgrade properly (Sandro Santilli)

#3982, ST\_AsEncodedPolyline supports LINESRING EMPTY and MULTIPOINT EMPTY (Darafei Praliaskouski)

#3975, ST\_Transform runs query on spatial\_ref\_sys without schema qualification. May cause restore issues. (Paul Ramsey)

## A.4 Release 2.3.5

Release date: 2017/11/15

This is a bug fix and performance improvement release.

### A.4.1 Bug Fixes and Enhancements

#3667, Fix for bug in geography ST\_Segmentize

#3926, Add missing 2.2.6 upgrade path

## A.5 Release 2.3.4

Release date: 2017/10/18

This is a bug fix and performance improvement release.

---

## A.5.1 Bug Fixes and Enhancements

PostgreSQL 10 support

- #3782, Memory leak in lwline\_from\_wkb\_state (Even Rouault)
- #3101, Fix buffer overflow in pgsq2shp (Sandro Santilli)
- #3786, ptarray null and heap issues on is\_closed
- #3795, Solaris build issues due to missing isfinite define (Julian Schauder)
- #3792, mark all 3D related including SFCGAL as parallel safe
- #3800, shp2pgsql-gui allow export of foreign tables, materialized views, and partitioned tables
- #3806, Reverse geocoder missing suffix direction when present
- #3698, loading census tabblock is broken
- #3839, loader tests sometimes crash because of variables not initialized also reenables loader tests to always run.
- #3774, Trigonometric length for CompoundCurves
- #3731, Crash on very small table of homogenous data
- #2836, Receiving ERROR: ExteriorRing: geom is not a polygon with ST\_ConcaveHull
- #3781, Not-quite curved CurvePolygon rejected by ST\_Contains
- #3818, Triangles unclosed in M should be parseable
- #3866, Rare crash generating TWKB with large coordinate values
- #3869, Fix build with "gold" linker
- #3845, Gracefully handle short-measure issue
- #3879, Division by zero in some arc cases
- #3878, Single defn of signum in header
- #3880, Undefined behaviour in TYPMOD\_GET\_SRID
- #3875, Fix undefined behaviour in shift operation
- #3874, lw\_dist2d\_pt\_arc division by zero
- #3882, undefined behaviour in zigzag with negative inputs
- #3891, undefined behaviour in pointarray\_to\_encoded\_polyline
- #3895, throw error on malformed WKB input
- #3907, Allocate enough space for all possible GBOX string outputs (Raúl Marín Rodríguez)

## A.6 Release 2.3.3

Release date: 2017/07/01

This is a bug fix and performance improvement release.

---

## A.6.1 Bug Fixes and Enhancements

- #3777, GROUP BY anomaly with empty geometries
- #3711, Azimuth error upon adding 2.5D edges to topology
- #3726, PDF manual from dblatex renders fancy quotes for programlisting (Mike Toews)
- #3738, raster: Using -s without -Y in raster2pgsql transforms raster data instead of setting srid
- #3744, ST\_Subdivide loses subparts of inverted geometries (Darafei Praliaskouski Komzpa)
- #3750, @ and ~ operator not always schema qualified in geometry and raster functions. Causes restore issues. (Shane StClair of Axiom Data Science)
- #3682, Strange fieldlength for boolean in result of pgsq2shp
- #3701, Escape double quotes issue in pgsq2shp
- #3704, ST\_AsX3D crashes on empty geometry
- #3730, Change ST\_Clip from Error to Notice when ST\_Clip can't compute a band

## A.7 Release 2.3.2

Release date: 2017/01/31

This is a bug fix and performance improvement release.

### A.7.1 Bug Fixes and Enhancements

- #3418, KNN recheck in 9.5+ fails with index returned tuples in wrong order
- #3675, Relationship functions not using an index in some cases
- #3680, PostGIS upgrade scripts missing GRANT for views
- #3683, Unable to update postgis after postgres pg\_upgrade going from < 9.5 to pg > 9.4
- #3688, ST\_AsLatLonText: round minutes

## A.8 Release 2.3.1

Release date: 2016/11/28

This is a bug fix and performance improvement release.

### A.8.1 Bug Fixes and Enhancements

- #1973, st\_concavehull() returns sometimes empty geometry collection Fix from gde
  - #3501, add raster constraint max extent exceeds array size limit for large tables
  - #3643, PostGIS not building on latest OSX XCode
  - #3644, Deadlock on interrupt
  - #3650, Mark ST\_Extent, ST\_3DExtent and ST\_Mem\* agg functions as parallel safe so they can be parallelized
  - #3652, Crash on Collection(MultiCurve())
  - #3656, Fix upgrade of aggregates from 2.2 or lower version
  - #3659, Crash caused by raster GUC define after CREATE EXTENSION using wrong memory context. (manaeem)
  - #3665, Index corruption and memory leak in BRIN indexes patch from Julien Rouhaud (Dalibo)
  - #3667, geography ST\_Segmentize bug patch from Hugo Mercier (Oslandia)
-

## A.9 Release 2.3.0

Release date: 2016/09/26

This is a new feature release, with new functions, improved performance, all relevant bug fixes from PostGIS 2.2.3, and other goodies.

### A.9.1 Important / Breaking Changes

#3466, Casting from box3d to geometry now returns a 3D geometry (Julien Rouhaud of Dalibo)

#3396, ST\_EstimatedExtent, throw WARNING instead of ERROR (Regina Obe)

### A.9.2 New Features

Add support for custom TOC in postgis\_restore.pl (Christoph Moench-Tegeder)

Add support for negative indexing in ST\_PointN and ST\_SetPoint (Rémi Cura)

Add parameters for geography ST\_Buffer (Thomas Bonfort)

TopoGeom\_addElement, TopoGeom\_remElement (Sandro Santilli)

populate\_topology\_layer (Sandro Santilli)

#454, ST\_WrapX and lwgeom\_wrapx (Sandro Santilli)

#1758, ST\_Normalize (Sandro Santilli)

#2236, shp2pgsql -d now emits "DROP TABLE IF EXISTS"

#2259, ST\_VoronoiPolygons and ST\_VoronoiLines (Dan Baston)

#2841 and #2996, ST\_MinimumBoundingRadius and new ST\_MinimumBoundingCircle implementation using Welzl's algorithm (Dan Baston)

#2991, Enable ST\_Transform to use PROJ.4 text (Mike Toews)

#3059, Allow passing per-dimension parameters in ST\_Expand (Dan Baston)

#3339, ST\_GeneratePoints (Paul Ramsey)

#3362, ST\_ClusterDBSCAN (Dan Baston)

#3364, ST\_GeometricMedian (Dan Baston)

#3391, Add table inheritance support in ST\_EstimatedExtent (Alessandro Pasotti)

#3424, ST\_MinimumClearance (Dan Baston)

#3428, ST\_Points (Dan Baston)

#3465, ST\_ClusterKMeans (Paul Ramsey)

#3469, ST\_MakeLine with MULTIPOINTs (Paul Norman)

#3549, Support PostgreSQL 9.6 parallel query mode, as far as possible (Paul Ramsey, Regina Obe)

#3557, Geometry function costs based on query stats (Paul Norman)

#3591, Add support for BRIN indexes. PostgreSQL 9.4+ required. (Giuseppe Broccolo of 2nd Quadrant, Julien Rouhaud and Ronan Dunklau of Dalibo)

#3496, Make postgis non-relocateable for extension install, schema qualify calls in functions (Regina Obe) Should resolve once and for all for extensions #3494, #3486, #3076

#3547, Update tiger geocoder to support TIGER 2016 and to support both http and ftp.

#3613, Segmentize geography using equal length segments (Hugo Mercier of Oslandia)

### A.9.3 Bug Fixes

All relevant bug fixes from PostGIS 2.2.3

#2841, ST\_MinimumBoundingCircle not covering original

#3604, pgcommon/Makefile.in orders CFLAGS incorrectly leading to wrong liblwgeom.h (Greg Troxel)

### A.9.4 Performance Enhancements

#75, Enhancement to PIP short circuit (Dan Baston)

#3383, Avoid deserializing small geometries during index operations (Dan Baston)

#3400, Minor optimization of PIP routines (Dan Baston)

Make adding a line to topology interruptible (Sandro Santilli)

Documentation updates from Mike Toews

## A.10 Release 2.2.2

Release date: 2016/03/22

This is a bug fix and performance improvement release.

### A.10.1 New Features

#3463, Fix crash on face-collapsing edge change

#3422, Improve ST\_Split robustness on standard precision double systems (arm64, ppc64el, s390c, powerpc, ...)

#3427, Update spatial\_ref\_sys to EPSG version 8.8

#3433, ST\_ClusterIntersecting incorrect for MultiPoints

#3435, ST\_AsX3D fix rendering of concave geometries

#3436, memory handling mistake in parray\_clone\_deep

#3437, ST\_Intersects incorrect for MultiPoints

#3461, ST\_GeomFromKML crashes Postgres when there are innerBoundaryIs and no outerBoundaryIs

#3429, upgrading to 2.3 or from 2.1 can cause loop/hang on some platforms

#3460, ST\_ClusterWithin 'Tolerance not defined' error after upgrade

#3490, Raster data restore issues, materialized views. Scripts postgis\_proc\_set\_search\_path.sql, rpostgis\_proc\_set\_search\_path.sql refer to [http://postgis.net/docs/manual-2.2/RT\\_FAQ.html#faq\\_raster\\_data\\_not\\_restore](http://postgis.net/docs/manual-2.2/RT_FAQ.html#faq_raster_data_not_restore)

#3426, failing POINT EMPTY tests on fun architectures

## A.11 Release 2.2.1

Release date: 2016/01/06

This is a bug fix and performance improvement release.

---

### A.11.1 New Features

#2232, avoid accumulated error in SVG rounding

#3321, Fix performance regression in topology loading

#3329, Fix robustness regression in TopoGeo\_addPoint

#3349, Fix installation path of postgis\_topology scripts

#3351, set endnodes isolation on ST\_RemoveIsoEdge (and lwt\_RemIsoEdge)

#3355, geography ST\_Segmentize has geometry bbox

#3359, Fix toTopoGeom loss of low-id primitives from TopoGeometry definition

#3360, \_raster\_constraint\_info\_scale invalid input syntax

#3375, crash in repeated point removal for collection(point)

#3378, Fix handling of hierarchical TopoGeometries in presence of multiple topologies

#3380, #3402, Decimate lines on topology load

#3388, #3410, Fix missing end-points in ST\_Removepoints

#3389, Buffer overflow in lwgeom\_to\_geojson

#3390, Compilation under Alpine Linux 3.2 gives an error when compiling the postgis and postgis\_topology extension

#3393, ST\_Area NaN for some polygons

#3401, Improve ST\_Split robustness on 32bit systems

#3404, ST\_ClusterWithin crashes backend

#3407, Fix crash on splitting a face or an edge defining multiple TopoGeometry objects

#3411, Clustering functions not using spatial index

#3412, Improve robustness of snapping step in TopoGeo\_addLinestring

#3415, Fix OSX 10.9 build under pkgsrc

Fix memory leak in lwt\_ChangeEdgeGeom [liblwgeom]

## A.12 Release 2.2.0

Release date: 2015/10/07

This is a new feature release, with new functions, improved performance, and other goodies.

### A.12.1 New Features

Topology API in liblwgeom (Sandro Santilli / Regione Toscana - SITA)

New lwgeom\_unaryunion method in liblwgeom

New lwgeom\_linemerge method in liblwgeom

New lwgeom\_is\_simple method in liblwgeom

#3169, Add SFCGAL 1.1 support: add ST\_3DDifference, ST\_3DUnion, ST\_Volume, ST\_MakeSolid, ST\_IsSolid (Vincent Mora / Oslandia)

#3169, ST\_ApproximateMedialAxis (Sandro Santilli)

ST\_CPAWithin (Sandro Santilli / Boundless)

---

Add |=| operator with CPA semantic and KNN support with PostgreSQL 9.5+ (Sandro Santilli / Boundless)

#3131, KNN support for the geography type (Paul Ramsey / CartoDB)

#3023, ST\_ClusterIntersecting / ST\_ClusterWithin (Dan Baston)

#2703, Exact KNN results for all geometry types, aka "KNN re-check" (Paul Ramsey / CartoDB)

#1137, Allow a tolerance value in ST\_RemoveRepeatedPoints (Paul Ramsey / CartoDB)

#3062, Allow passing M factor to ST\_Scale (Sandro Santilli / Boundless)

#3139, ST\_BoundingDiagonal (Sandro Santilli / Boundless)

#3129, ST\_IsValidTrajectory (Sandro Santilli / Boundless)

#3128, ST\_ClosestPointOfApproach (Sandro Santilli / Boundless)

#3152, ST\_DistanceCPA (Sandro Santilli / Boundless)

Canonical output for index key types

ST\_SwapOrdinates (Sandro Santilli / Boundless)

#2918, Use GeographicLib functions for geodetics (Mike Toews)

#3074, ST\_Subdivide to break up large geometry (Paul Ramsey / CartoDB)

#3040, KNN GiST index based centroid (<<->) n-D distance operators (Sandro Santilli / Boundless)

Interruptibility API for liblwgeom (Sandro Santilli / CartoDB)

#2939, ST\_ClipByBox2D (Sandro Santilli / CartoDB)

#2247, ST\_Retile and ST\_CreateOverview: in-db raster overviews creation (Sandro Santilli / Vizzuality)

#899, -m shp2pgsql attribute names mapping -m switch (Regina Obe / Sandro Santilli)

#1678, Added GUC postgis.gdal\_datapath to specify GDAL config variable GDAL\_DATA

#2843, Support reprojection on raster import (Sandro Santilli / Vizzuality)

#2349, Support for encoded\_polyline input/output (Kashif Rasul)

#2159, report libjson version from postgis\_full\_version()

#2770, ST\_MemSize(raster)

Add postgis\_noop(raster)

Added missing variants of ST\_TPI(), ST\_TRI() and ST\_Roughness()

Added GUC postgis.gdal\_enabled\_drivers to specify GDAL config variable GDAL\_SKIP

Added GUC postgis.enable\_outdb\_rasters to enable access to rasters with out-db bands

#2387, address\_standardizer extension as part of PostGIS (Stephen Woodbridge / imaptools.com, Walter Sinclair, Regina Obe)

#2816, address\_standardizer\_data\_us extension provides reference lex,gaz,rules for address\_standardizer (Stephen Woodbridge / imaptools.com, Walter Sinclair, Regina Obe)

#2341, New mask parameter for ST\_MapAlgebra

#2397, read encoding info automatically in shapefile loader

#2430, ST\_ForceCurve

#2565, ST\_SummaryStatsAgg()

#2567, ST\_CountAgg()

#2632, ST\_AsGML() support for curved features

#2652, Add --upgrade-path switch to run\_test.pl

#2754, sfcgal wrapped as an extension

#2227, Simplification with Visvalingam-Whyatt algorithm ST\_SimplifyVW, ST\_SetEffectiveArea (Nicklas Avén)

Functions to encode and decode TWKB ST\_AsTWKB, ST\_GeomFromTWKB (Paul Ramsey / Nicklas Avén / CartoDB)

## A.12.2 Enhancements

- #3223, Add memcmp short-circuit to ST\_Equals (Daniel Baston)
- #3227, Tiger geocoder upgraded to support Tiger 2015 census
- #2278, Make liblwgeom compatible between minor releases
- #897, ST\_AsX3D support for GeoCoordinates and systems "GD" "WE" ability to flip x/y axis (use option = 2, 3)
- ST\_Split: allow splitting lines by multilines, multipoints and (multi)polygon boundaries
- #3070, Simplify geometry type constraint
- #2839, Implement selectivity estimator for functional indexes, speeding up spatial queries on raster tables. (Sandro Santilli / Vizzuality)
- #2361, Added spatial\_index column to raster\_columns view
- #2390, Testsuite for pgsq2shp
- #2527, Added -k flag to raster2pgsql to skip checking that band is NODATA
- #2616, Reduce text casts during topology building and export
- #2717, support startpoint, endpoint, pointn, numpoints for compoundcurve
- #2747, Add support for GDAL 2.0
- #2754, SFCGAL can now be installed with CREATE EXTENSION (Vincent Mora @ Oslandia)
- #2828, Convert ST\_Envelope(raster) from SQL to C
- #2829, Shortcut ST\_Clip(raster) if geometry fully contains the raster and no NODATA specified
- #2906, Update tiger geocoder to handle tiger 2014 data
- #3048, Speed up geometry simplification (J.Santana @ CartoDB)
- #3092, Slow performance of geometry\_columns with many tables

## A.13 Release 2.1.8

Release date: 2015-07-07

This is a critical bug fix release.

### A.13.1 Bug Fixes

- #3159, do not force a bbox cache on ST\_Affine
  - #3018, GROUP BY geography sometimes returns duplicate rows
  - #3084, shp2pgsql - illegal number format when specific system locale set
  - #3094, Malformed GeoJSON inputs crash backend
  - #3104, st\_asgml introduces random characters in ID field
  - #3155, Remove liblwgeom.h on make uninstall
  - #3177, gserialized\_is\_empty cannot handle nested empty cases
- Fix crash in ST\_LineLocatePoint

## A.14 Release 2.1.7

Release date: 2015-03-30

This is a critical bug fix release.

### A.14.1 Bug Fixes

#3086, ST\_DumpValues() crashes backend on cleanup with invalid band indexes

#3088, Do not (re)define strcasestr in a liblwgeom.h

#3094, Malformed GeoJSON inputs crash backend

## A.15 Release 2.1.6

Release date: 2015-03-20

This is a bug fix and performance improvement release.

### A.15.1 Enhancements

#3000, Ensure edge splitting and healing algorithms use indexes

#3048, Speed up geometry simplification (J.Santana @ CartoDB)

#3050, Speed up geometry type reading (J.Santana @ CartoDB)

### A.15.2 Bug Fixes

#2941, allow geography columns with SRID other than 4326

#3069, small objects getting inappropriately fluffed up w/ boxes

#3068, Have postgis\_typmod\_dims return NULL for unconstrained dims

#3061, Allow duplicate points in JSON, GML, GML ST\_GeomFrom\* functions

#3058, Fix ND-GiST picksplit method to split on the best plane

#3052, Make operators <-> and <#> available for PostgreSQL < 9.1

#3045, Fix dimensionality confusion in &&& operator

#3016, Allow unregistering layers of corrupted topologies

#3015, Avoid exceptions from TopologySummary

#3020, ST\_AddBand out-db bug where height using width value

#3031, Allow restore of Geometry(Point) tables dumped with empties in them

## A.16 Release 2.1.5

Release date: 2014-12-18

This is a bug fix and performance improvement release.

---

### A.16.1 Enhancements

#2933, Speedup construction of large multi-geometry objects

### A.16.2 Bug Fixes

#2947, Fix memory leak in lwgeom\_make\_valid for single-component collection input

#2949, Fix memory leak in lwgeom\_mindistance2d for curve input

#2931, BOX representation is case sensitive

#2942, PostgreSQL 9.5 support

#2953, 2D stats not generated when Z/M values are extreme

#3009, Geography cast may effect underlying tuple

## A.17 Release 2.1.4

Release date: 2014-09-10

This is a bug fix and performance improvement release.

### A.17.1 Enhancements

#2745, Speedup ST\_Simplify calls against points

#2747, Support for GDAL 2.0

#2749, Make rtpostgis\_upgrade\_20\_21.sql ACID

#2811, Do not specify index names when loading shapefiles/rasters

#2829, Shortcut ST\_Clip(raster) if geometry fully contains the raster and no NODATA specified

#2895, Raise cost of ST\_ConvexHull(raster) to 300 for better query plans

### A.17.2 Bug Fixes

#2605, armel: \_ST\_Covers() returns true for point in hole

#2911, Fix output scale on ST\_Rescale/ST\_Resample/ST\_Resize of rasters with scale 1/-1 and offset 0/0.

Fix crash in ST\_Union(raster)

#2704, ST\_GeomFromGML() does not work properly with array of gml:pos (Even Roualt)

#2708, updategeometrysrid doesn't update srid check when schema not specified. Patch from Marc Jansen

#2720, lwpoly\_add\_ring should update maxrings after realloc

#2759, Fix postgis\_restore.pl handling of multiline object comments embedding sql comments

#2774, fix undefined behavior in parray\_calculate\_gbox\_geodetic

Fix potential memory fault in ST\_MakeValid

#2784, Fix handling of bogus argument to --with-sfcgal

#2772, Premature memory free in RASTER\_getBandPath (ST\_BandPath)

#2755, Fix regressions tests against all versions of SFCGAL

#2775, lwline\_from\_lwmpoint leaks memory

- #2802, ST\_MapAlgebra checks for valid callback function return value
- #2803, ST\_MapAlgebra handles no userarg and STRICT callback function
- #2834, ST\_Estimated\_Extent and mixedCase table names (regression bug)
- #2845, Bad geometry created from ST\_AddPoint
- #2870, Binary insert into geography column results geometry being inserted
- #2872, make install builds documentation (Greg Troxell)
- #2819, find isfinite or replacement on Centos5 / Solaris
- #2899, geocode limit 1 not returning best answer (tiger geocoder)
- #2903, Unable to compile on FreeBSD
- #2927 reverse\_geocode not filling in direction prefix (tiger geocoder) get rid of deprecated ST\_Line\_Locate\_Point called

## A.18 Release 2.1.3

Release date: 2014/05/13

This is a bug fix and security release.

### A.18.1 Important changes

Starting with this version offline raster access and use of GDAL drivers are disabled by default.

An environment variable is introduced to allow for enabling specific GDAL drivers: `POSTGIS_GDAL_ENABLED_DRIVERS`. By default, all GDAL drivers are disabled

An environment variable is introduced to allow for enabling out-db raster bands: `POSTGIS_ENABLE_OUTDB_RASTERS`. By default, out-db raster bands are disabled

The environment variables must be set for the PostgreSQL process, and determines the behavior of the whole cluster.

### A.18.2 Bug Fixes

- #2697, invalid GeoJSON Polygon input crashes server process
- #2700, Fix dumping of higher-dimension datasets with null rows
- #2706, ST\_DumpPoints of EMPTY geometries crashes server

## A.19 Release 2.1.2

Release date: 2014/03/31

This is a bug fix release, addressing issues that have been filed since the 2.1.1 release.

### A.19.1 Bug Fixes

- #2666, Error out at configure time if no SQL preprocessor can be found
- #2534, st\_distance returning incorrect results for large geographies
- #2539, Check for json-c/json.h presence/usability before json/json.h
- #2543, invalid join selectivity error from simple query

- #2546, GeoJSON with string coordinates parses incorrectly
- #2547, Fix ST\_Simplify(TopoGeometry) for hierarchical topogeoms
- #2552, Fix NULL raster handling in ST\_AsPNG, ST\_AsTIFF and ST\_AsJPEG
- #2555, Fix parsing issue of range arguments of ST\_Reclass
- #2556, geography ST\_Intersects results depending on insert order
- #2580, Do not allow installing postgis twice in the same database
- #2589, Remove use of unnecessary void pointers
- #2607, Cannot open more than 1024 out-db files in one process
- #2610, Ensure face splitting algorithm uses the edge index
- #2615, EstimatedExtent (and hence, underlying stats) gathering wrong bbox
- #2619, Empty rings array in GeoJSON polygon causes crash
- #2634, regression in sphere distance code
- #2638, Geography distance on M geometries sometimes wrong
- #2648, #2653, Fix topology functions when "topology" is not in search\_path
- #2654, Drop deprecated calls from topology
- #2655, Let users without topology privileges call postgis\_full\_version()
- #2674, Fix missing operator = and hash\_raster\_ops opclass on raster
- #2675, #2534, #2636, #2634, #2638, Geography distance issues with tree optimization

## A.19.2 Enhancements

- #2494, avoid memcpy in GiST index (hayamiz)
- #2560, soft upgrade: avoid drop/recreate of aggregates that hadn't changed

## A.20 Release 2.1.1

Release date: 2013/11/06

This is a bug fix release, addressing issues that have been filed since the 2.1.0 release.

### A.20.1 Important Changes

- #2514, Change raster license from GPL v3+ to v2+, allowing distribution of PostGIS Extension as GPLv2.

### A.20.2 Bug Fixes

- #2396, Make regression tests more endian-agnostic
- #2434, Fix ST\_Intersection(geog,geog) regression in rare cases
- #2454, Fix behavior of ST\_PixelAsXXX functions regarding exclude\_nodata\_value parameter
- #2489, Fix upgrades from 2.0 leaving stale function signatures
- #2525, Fix handling of SRID in nested collections
- #2449, Fix potential infinite loop in index building
- #2493, Fix behavior of ST\_DumpValues when passed an empty raster
- #2502, Fix postgis\_topology\_scripts\_installed() install schema
- #2504, Fix segfault on bogus pgsqll2shp call
- #2512, Support for foreign tables and materialized views in raster\_columns and raster\_overviews

## A.20.3 Enhancements

#2478, support for tiger 2013

#2463, support for exact length calculations on arc geometries

## A.21 Release 2.1.0

Release date: 2013/08/17

This is a minor release addressing both bug fixes and performance and functionality enhancements addressing issues since 2.0.3 release. If you are upgrading from 2.0+, only a soft upgrade is required. If you are upgrading from 1.5 or earlier, a hard upgrade is required.

### A.21.1 Important / Breaking Changes

#1653, Removed srid parameter from ST\_Resample(raster) and variants with reference raster no longer apply reference raster's SRID.

#1962 ST\_Segmentize - As a result of the introduction of geography support, The construct: `SELECT ST_Segmentize('LINESTRING(1 2, 3 4)', 0.5);` will result in ambiguous function error

#2026, ST\_Union(raster) now unions all bands of all rasters

#2089, liblwgeom: lwgeom\_set\_handlers replaces lwgeom\_init\_allocators.

#2150, regular\_blocking is no longer a constraint. column of same name in raster\_columns now checks for existence of spatially\_unique and coverage\_tile constraints

ST\_Intersects(raster, geometry) behaves in the same manner as ST\_Intersects(geometry, raster).

point variant of ST\_SetValue(raster) previously did not check SRID of input geometry and raster.

ST\_Hillshade parameters azimuth and altitude are now in degrees instead of radians.

ST\_Slope and ST\_Aspect return pixel values in degrees instead of radians.

#2104, ST\_World2RasterCoord, ST\_World2RasterCoordX and ST\_World2RasterCoordY renamed to ST\_WorldToRasterCoord, ST\_WorldToRasterCoordX and ST\_WorldToRasterCoordY. ST\_Raster2WorldCoord, ST\_Raster2WorldCoordX and ST\_Raster2WorldCoordY renamed to ST\_RasterToWorldCoord, ST\_RasterToWorldCoordX and ST\_RasterToWorldCoordY

ST\_Estimated\_Extent renamed to ST\_EstimatedExtent

ST\_Line\_Interpolate\_Point renamed to ST\_LineInterpolatePoint

ST\_Line\_Substring renamed to ST\_LineSubstring

ST\_Line\_Locate\_Point renamed to ST\_LineLocatePoint

ST\_Force\_XXX renamed to ST\_ForceXXX

ST\_MapAlgebraFctNgb and 1 and 2 raster variants of ST\_MapAlgebraFct. Use ST\_MapAlgebra instead

1 and 2 raster variants of ST\_MapAlgebraExpr. Use expression variants of ST\_MapAlgebra instead

### A.21.2 New Features

- Refer to [http://postgis.net/docs/manual-2.1/PostGIS\\_Special\\_Functions\\_Index.html#NewFunctions\\_2\\_1](http://postgis.net/docs/manual-2.1/PostGIS_Special_Functions_Index.html#NewFunctions_2_1) for complete list of new functions

#310, ST\_DumpPoints converted to a C function (Nathan Wagner) and much faster

#739, UpdateRasterSRID()

#945, improved join selectivity, N-D selectivity calculations, user accessible selectivity and stats reader functions for testing (Paul Ramsey / OpenGeo)

toTopoGeom with TopoGeometry sink (Sandro Santilli / Vizzuality)

clearTopoGeom (Sandro Santilli / Vizzuality)

ST\_Segmentize(geography) (Paul Ramsey / OpenGeo)

ST\_DelaunayTriangles (Sandro Santilli / Vizzuality)

ST\_NearestValue, ST\_Neighborhood (Bborie Park / UC Davis)

ST\_PixelAsPoint, ST\_PixelAsPoints (Bborie Park / UC Davis)

ST\_PixelAsCentroid, ST\_PixelAsCentroids (Bborie Park / UC Davis)

ST\_Raster2WorldCoord, ST\_World2RasterCoord (Bborie Park / UC Davis)

Additional raster/raster spatial relationship functions (ST\_Contains, ST\_ContainsProperly, ST\_Covers, ST\_CoveredBy, ST\_Disjoint, ST\_Overlaps, ST\_Touches, ST\_Within, ST\_DWithin, ST\_DFullyWithin) (Bborie Park / UC Davis)

Added array variants of ST\_SetValues() to set many pixel values of a band in one call (Bborie Park / UC Davis)

#1293, ST\_Resize(raster) to resize rasters based upon width/height

#1627, package tiger\_geocoder as a PostgreSQL extension

#1643, #2076, Upgrade tiger geocoder to support loading tiger 2011 and 2012 (Regina Obe / Paragon Corporation) Funded by Hunter Systems Group

GEOMETRYCOLLECTION support for ST\_MakeValid (Sandro Santilli / Vizzuality)

#1709, ST\_NotSameAlignmentReason(raster, raster)

#1818, ST\_GeomFromGeoHash and friends (Jason Smith (darkpanda))

#1856, reverse geocoder rating setting for prefer numbered highway name

ST\_PixelOfValue (Bborie Park / UC Davis)

Casts to/from PostgreSQL geotypes (point/path/polygon).

Added geomval array variant of ST\_SetValues() to set many pixel values of a band using a set of geometries and corresponding values in one call (Bborie Park / UC Davis)

ST\_Tile(raster) to break up a raster into tiles (Bborie Park / UC Davis)

#1895, new r-tree node splitting algorithm (Alex Korotkov)

#2011, ST\_DumpValues to output raster as array (Bborie Park / UC Davis)

#2018, ST\_Distance support for CircularString, CurvePolygon, MultiCurve, MultiSurface, CompoundCurve

#2030, n-raster (and n-band) ST\_MapAlgebra (Bborie Park / UC Davis)

#2193, Utilize PAGC parser as drop in replacement for tiger normalizer (Steve Woodbridge, Regina Obe)

#2210, ST\_MinConvexHull(raster)

lwgeom\_from\_geojson in liblwgeom (Sandro Santilli / Vizzuality)

#1687, ST\_Simplify for TopoGeometry (Sandro Santilli / Vizzuality)

#2228, TopoJSON output for TopoGeometry (Sandro Santilli / Vizzuality)

#2123, ST\_FromGDALRaster

#613, ST\_SetGeoReference with numerical parameters instead of text

#2276, ST\_AddBand(raster) variant for out-db bands

#2280, ST\_Summary(raster)

#2163, ST\_TPI for raster (Nathaniel Clay)

#2164, ST\_TRI for raster (Nathaniel Clay)

#2302, ST\_Roughness for raster (Nathaniel Clay)

#2290, ST\_ColorMap(raster) to generate RGBA bands

#2254, Add SFCGAL backend support. (Backend selection through `postgis.backend` var) Functions available both through GEOS or SFCGAL: ST\_Intersects, ST\_3DIntersects, ST\_Intersection, ST\_Area, ST\_Distance, ST\_3DDistance New functions available only with SFCGAL backend: ST\_3DIntersection, ST\_Tessellate, ST\_3DArea, ST\_Extrude, ST\_ForceLHR ST\_Orientation, ST\_Minkowski, ST\_StraightSkeleton `postgis_sfcgal_version` New function available in PostGIS: ST\_ForceSFS (Olivier Courtin and Hugo Mercier / Oslandia)

### A.21.3 Enhancements

For detail of new functions and function improvements, please refer to Section 14.12.4.

Much faster raster ST\_Union, ST\_Clip and many more function additions operations

For geometry/geography better planner selectivity and a lot more functions.

#823, tiger geocoder: Make loader\_generate\_script download portion less greedy

#826, raster2pgsql no longer defaults to padding tiles. Flag -P can be used to pad tiles

#1363, ST\_AddBand(raster, ...) array version rewritten in C

#1364, ST\_Union(raster, ...) aggregate function rewritten in C

#1655, Additional default values for parameters of ST\_Slope

#1661, Add aggregate variant of ST\_SameAlignment

#1719, Add support for Point and GeometryCollection ST\_MakeValid inputs

#1780, support ST\_GeoHash for geography

#1796, Big performance boost for distance calculations in geography

#1802, improved function interruptibility.

#1823, add parameter in ST\_AsGML to use id column for GML 3 output (become mandatory since GML 3.2.1)

#1856, tiger geocoder: reverse geocoder rating setting for prefer numbered highway name

#1938, Refactor basic ST\_AddBand to add multiple new bands in one call

#1978, wrong answer when calculating length of a closed circular arc (circle)

#1989, Preprocess input geometry to just intersection with raster to be clipped

#2021, Added multi-band support to ST\_Union(raster, ...) aggregate function

#2006, better support of ST\_Area(geography) over poles and dateline

#2065, ST\_Clip(raster, ...) now a C function

#2069, Added parameters to ST\_Tile(raster) to control padding of tiles

#2078, New variants of ST\_Slope, ST\_Aspect and ST\_HillShade to provide solution to handling tiles in a coverage

#2097, Added RANGE uniontype option for ST\_Union(raster)

#2105, Added ST\_Transform(raster) variant for aligning output to reference raster

#2119, Rasters passed to ST\_Resample(), ST\_Rescale(), ST\_Reskew(), and ST\_SnapToGrid() no longer require an SRID

#2141, More verbose output when constraints fail to be added to a raster column

#2143, Changed blocksize constraint of raster to allow multiple values

#2148, Addition of coverage\_tile constraint for raster

#2149, Addition of spatially\_unique constraint for raster

TopologySummary output now includes unregistered layers and a count of missing TopoGeometry objects from their natural layer.

ST\_HillShade(), ST\_Aspect() and ST\_Slope() have one new optional parameter to interpolate NODATA pixels before running the operation.

Point variant of ST\_SetValue(raster) is now a wrapper around geomval variant of ST\_SetValues(rast).

Proper support for raster band's isnodata flag in core API and loader.

Additional default values for parameters of ST\_Aspect and ST\_HillShade

#2178, ST\_Summary now advertises presence of known srid with an [S] flag

#2202, Make libjson-c optional (--without-json configure switch)

#2213, Add support libjson-c 0.10+

#2231, raster2pgsql supports user naming of filename column with -n

#2200, ST\_Union(raster, uniontype) unions all bands of all rasters

#2264, postgis\_restore.pl support for restoring into databases with postgis in a custom schema

#2244, emit warning when changing raster's georeference if raster has out-db bands

#2222, add parameter OutAsIn to flag whether ST\_AsBinary should return out-db bands as in-db bands

#### A.21.4 Fixes

#1839, handling of subdatasets in GeoTIFF in raster2pgsql.

#1840, fix logic of when to compute # of tiles in raster2pgsql.

#1870, align the docs and actual behavior of raster's ST\_Intersects

#1872, fix ST\_ApproxSummaryStats to prevent division by zero

#1875, ST\_SummaryStats returns NULL for all parameters except count when count is zero

#1932, fix raster2pgsql of syntax for index tablespaces

#1936, ST\_GeomFromGML on CurvePolygon causes server crash

#1939, remove custom data types: summaryStats, histogram, quantile, valuecount

#1951, remove crash on zero-length linestrings

#1957, ST\_Distance to a one-point LineString returns NULL

#1976, Geography point-in-ring code overhauled for more reliability

#1981, cleanup of unused variables causing warnings with gcc 4.6+

#1996, support POINT EMPTY in GeoJSON output

#2062, improve performance of distance calculations

#2057, Fixed linking issue for raster2pgsql to libpq

#2077, Fixed incorrect values returning from ST\_Hillshade()

#2019, ST\_FlipCoordinates does not update bbox

#2100, ST\_AsRaster may not return raster with specified pixel type

#2126, Better handling of empty rasters from ST\_ConvexHull()

#2165, ST\_NumPoints regression failure with CircularString

#2168, ST\_Distance is not always commutative

#2182, Fix issue with outdb rasters with no SRID and ST\_Resize

- #2188, Fix function parameter value overflow that caused problems when copying data from a GDAL dataset
- #2198, Fix incorrect dimensions used when generating bands of out-db rasters in ST\_Tile()
- #2201, ST\_GeoHash wrong on boundaries
- #2203, Changed how rasters with unknown SRID and default geotransform are handled when passing to GDAL Warp API
- #2215, Fixed raster exclusion constraint for conflicting name of implicit index
- #2251, Fix bad dimensions when rescaling rasters with default geotransform matrix
- #2133, Fix performance regression in expression variant of ST\_MapAlgebra
- #2257, GBOX variables not initialized when testing with empty geometries
- #2271, Prevent parallel make of raster
- #2282, Fix call to undefined function nd\_stats\_to\_grid() in debug mode
- #2307, ST\_MakeValid outputs invalid geometries
- #2309, Remove confusing INFO message when trying to get SRS info
- #2336, FIPS 20 (KS) causes wildcard expansion to wget all files
- #2348, Provide raster upgrade path for 2.0 to 2.1
- #2351, st\_distance between geographies wrong
- #2359, Fix handling of schema name when adding overview constraints
- #2371, Support GEOS versions with more than 1 digit in micro
- #2383, Remove unsafe use of \` from raster warning message
- #2384, Incorrect variable datatypes for ST\_Neighborhood

### A.21.5 Known Issues

- #2111, Raster bands can only reference the first 256 bands of out-db rasters

## A.22 Release 2.0.5

Release date: 2014/03/31

This is a bug fix release, addressing issues that have been filed since the 2.0.4 release. If you are using PostGIS 2.0+ a soft upgrade is required. For users of PostGIS 1.5 or below, a hard upgrade is required.

### A.22.1 Bug Fixes

- #2494, avoid memcpy in GIST index
- #2502, Fix postgis\_topology\_scripts\_installed() install schema
- #2504, Fix segfault on bogus pgsq2shp call
- #2528, Fix memory leak in ST\_Split / lwline\_split\_by\_line
- #2532, Add missing raster/geometry commutator operators
- #2533, Remove duplicated signatures
- #2552, Fix NULL raster handling in ST\_AsPNG, ST\_AsTIFF and ST\_AsJPEG
- #2555, Fix parsing issue of range arguments of ST\_Reclass
- #2589, Remove use of unnecessary void pointers

- #2607, Cannot open more than 1024 out-db files in process
- #2610, Ensure face splitting algorithm uses the edge index
- #2619, Empty ring array in GeoJSON polygon causes crash
- #2638, Geography distance on M geometries sometimes wrong

## A.22.2 Important Changes

- ##2514, Change raster license from GPL v3+ to v2+, allowing distribution of PostGIS Extension as GPLv2.

## A.23 Release 2.0.4

Release date: 2013/09/06

This is a bug fix release, addressing issues that have been filed since the 2.0.3 release. If you are using PostGIS 2.0+ a soft upgrade is required. For users of PostGIS 1.5 or below, a hard upgrade is required.

### A.23.1 Bug Fixes

- #2110, Equality operator between EMPTY and point on origin
  - Allow adding points at precision distance with TopoGeo\_addPoint
  - #1968, Fix missing edge from toTopoGeom return
  - #2165, ST\_NumPoints regression failure with CircularString
  - #2168, ST\_Distance is not always commutative
  - #2186, gui progress bar updates too frequent
  - #2201, ST\_GeoHash wrong on boundaries
  - #2257, GBOX variables not initialized when testing with empty geometries
  - #2271, Prevent parallel make of raster
  - #2267, Server crash from analyze table
  - #2277, potential segfault removed
  - #2307, ST\_MakeValid outputs invalid geometries
  - #2351, st\_distance between geographies wrong
  - #2359, Incorrect handling of schema for overview constraints
  - #2371, Support GEOS versions with more than 1 digit in micro
  - #2372, Cannot parse space-padded KML coordinates
  - Fix build with systemwide liblwgeom installed
  - #2383, Fix unsafe use of \ in warning message
  - #2410, Fix segmentize of collinear curve
  - #2412, ST\_LineToCurve support for lines with less than 4 vertices
  - #2415, ST\_Multi support for COMPOUNDCURVE and CURVEPOLYGON
  - #2420, ST\_LineToCurve: require at least 8 edges to define a full circle
  - #2423, ST\_LineToCurve: require all arc edges to form the same angle
  - #2424, ST\_CurveToLine: add support for COMPOUNDCURVE in MULTICURVE
  - #2427, Make sure to retain first point of curves on ST\_CurveToLine
-

## A.23.2 Enhancements

#2269, Avoid uselessly detoasting full geometries on ANALYZE

## A.23.3 Known Issues

#2111, Raster bands can only reference the first 256 bands of out-db rasters

## A.24 Release 2.0.3

Release date: 2013/03/01

This is a bug fix release, addressing issues that have been filed since the 2.0.2 release. If you are using PostGIS 2.0+ a soft upgrade is required. For users of PostGIS 1.5 or below, a hard upgrade is required.

### A.24.1 Bug Fixes

#2126, Better handling of empty rasters from ST\_ConvexHull()

#2134, Make sure to process SRS before passing it off to GDAL functions

Fix various memory leaks in liblwgeom

#2173, Fix robustness issue in splitting a line with own vertex also affecting topology building (#2172)

#2174, Fix usage of wrong function lwpoly\_free()

#2176, Fix robustness issue with ST\_ChangeEdgeGeom

#2184, Properly copy topologies with Z value

postgis\_restore.pl support for mixed case geometry column name in dumps

#2188, Fix function parameter value overflow that caused problems when copying data from a GDAL dataset

#2216, More memory errors in MultiPolygon GeoJSON parsing (with holes)

Fix Memory leak in GeoJSON parser

### A.24.2 Enhancements

#2141, More verbose output when constraints fail to be added to a raster column

Speedup ST\_ChangeEdgeGeom

## A.25 Release 2.0.2

Release date: 2012/12/03

This is a bug fix release, addressing issues that have been filed since the 2.0.1 release.

---

## A.25.1 Bug Fixes

- #1287, Drop of "gist\_geometry\_ops" broke a few clients package of legacy\_gist.sql for these cases
  - #1391, Errors during upgrade from 1.5
  - #1828, Poor selectivity estimate on ST\_DWithin
  - #1838, error importing tiger/line data
  - #1869, ST\_AsBinary is not unique added to legacy\_minor/legacy.sql scripts
  - #1885, Missing field from tabblock table in tiger2010 census\_loader.sql
  - #1891, Use LDFLAGS environment when building liblwgeom
  - #1900, Fix pgsq2shp for big-endian systems
  - #1932, Fix raster2pgsql for invalid syntax for setting index tablespace
  - #1936, ST\_GeomFromGML on CurvePolygon causes server crash
  - #1955, ST\_ModEdgeHeal and ST\_NewEdgeHeal for doubly connected edges
  - #1957, ST\_Distance to a one-point LineString returns NULL
  - #1976, Geography point-in-ring code overhauled for more reliability
  - #1978, wrong answer calculating length of closed circular arc (circle)
  - #1981, Remove unused but set variables as found with gcc 4.6+
  - #1987, Restore 1.5.x behaviour of ST\_Simplify
  - #1989, Preprocess input geometry to just intersection with raster to be clipped
  - #1991, geocode really slow on PostgreSQL 9.2
  - #1996, support POINT EMPTY in GeoJSON output
  - #1998, Fix ST\_{Mod,New}EdgeHeal joining edges sharing both endpoints
  - #2001, ST\_CurveToLine has no effect if the geometry doesn't actually contain an arc
  - #2015, ST\_IsEmpty('POLYGON(EMPTY)') returns False
  - #2019, ST\_FlipCoordinates does not update bbox
  - #2025, Fix side location conflict at TopoGeo\_AddLineString
  - #2026, improve performance of distance calculations
  - #2033, Fix adding a splitting point into a 2.5d topology
  - #2051, Fix excess of precision in ST\_AsGeoJSON output
  - #2052, Fix buffer overflow in lwgeom\_to\_geojson
  - #2056, Fixed lack of SRID check of raster and geometry in ST\_SetValue()
  - #2057, Fixed linking issue for raster2pgsql to libpq
  - #2060, Fix "dimension" check violation by GetTopoGeomElementArray
  - #2072, Removed outdated checks preventing ST\_Intersects(raster) from working on out-db bands
  - #2077, Fixed incorrect answers from ST\_Hillshade(raster)
  - #2092, Namespace issue with ST\_GeomFromKML,ST\_GeomFromGML for libxml 2.8+
  - #2099, Fix double free on exception in ST\_OffsetCurve
  - #2100, ST\_AsRaster() may not return raster with specified pixel type
  - #2108, Ensure ST\_Line\_Interpolate\_Point always returns POINT
-

- #2109, Ensure ST\_Centroid always returns POINT
  - #2117, Ensure ST\_PointOnSurface always returns POINT
  - #2129, Fix SRID in ST\_Homogenize output with collection input
  - #2130, Fix memory error in MultiPolygon GeoJson parsing
- Update URL of Maven jar

## A.25.2 Enhancements

- #1581, ST\_Clip(raster, ...) no longer imposes NODATA on a band if the corresponding band from the source raster did not have NODATA
- #1928, Accept array properties in GML input multi-geom input (Kashif Rasul and Shoaib Burq / SpacialDB)
- #2082, Add indices on start\_node and end\_node of topology edge tables
- #2087, Speedup topology.GetRingEdges using a recursive CTE

## A.26 Release 2.0.1

Release date: 2012/06/22

This is a bug fix release, addressing issues that have been filed since the 2.0.0 release.

### A.26.1 Bug Fixes

- #1264, fix st\_dwithin(geog, geog, 0).
- #1468 shp2pgsql-gui table column schema get shifted
- #1694, fix building with clang. (vince)
- #1708, improve restore of pre-PostGIS 2.0 backups.
- #1714, more robust handling of high topology tolerance.
- #1755, ST\_GeographyFromText support for higher dimensions.
- #1759, loading transformed shapefiles in raster enabled db.
- #1761, handling of subdatasets in NetCDF, HDF4 and HDF5 in raster2pgsql.
- #1763, topology.toTopoGeom use with custom search\_path.
- #1766, don't let ST\_RemEdge\* destroy peripheral TopoGeometry objects.
- #1774, Clearer error on setting an edge geometry to an invalid one.
- #1775, ST\_ChangeEdgeGeom collision detection with 2-vertex target.
- #1776, fix ST\_SymDifference(empty, geom) to return geom.
- #1779, install SQL comment files.
- #1782, fix spatial reference string handling in raster.
- #1789, fix false edge-node crossing report in ValidateTopology.
- #1790, fix toTopoGeom handling of duplicated primitives.
- #1791, fix ST\_Azimuth with very close but distinct points.
- #1797, fix (ValidateTopology(xxx)).\* syntax calls.
- #1805, put back the 900913 SRID entry.

- #1813, Only show readable relations in metadata tables.
- #1819, fix floating point issues with ST\_World2RasterCoord and ST\_Raster2WorldCoord variants.
- #1820 compilation on 9.2beta1.
- #1822, topology load on PostgreSQL 9.2beta1.
- #1825, fix prepared geometry cache lookup
- #1829, fix uninitialized read in GeoJSON parser
- #1834, revise postgis extension to only backup user specified spatial\_ref\_sys
- #1839, handling of subdatasets in GeoTIFF in raster2pgsql.
- #1840, fix logic of when to compute # of tiles in raster2pgsql.
- #1851, fix spatial\_ref\_system parameters for EPSG:3844
- #1857, fix failure to detect endpoint mismatch in ST\_AddEdge\*Face\*
- #1865, data loss in postgis\_restore.pl when data rows have leading dashes.
- #1867, catch invalid topology name passed to topogeo\_add\*
- #1872, fix ST\_ApproxSummarystats to prevent division by zero
- #1873, fix ptarray\_locate\_point to return interpolated Z/M values for on-the-line case
- #1875, ST\_SummaryStats returns NULL for all parameters except count when count is zero
- #1881, shp2pgsql-gui -- editing a field sometimes triggers removing row
- #1883, Geocoder install fails trying to run create\_census\_base\_tables() (Brian Panulla)

## A.26.2 Enhancements

More detailed exception message from topology editing functions.

- #1786, improved build dependencies
- #1806, speedup of ST\_BuildArea, ST\_MakeValid and ST\_GetFaceGeometry.
- #1812, Add lwgeom\_normalize in LIBLWGEOM for more stable testing.

## A.27 Release 2.0.0

Release date: 2012/04/03

This is a major release. A hard upgrade is required. Yes this means a full dump reload and some special preparations if you are using obsolete functions. Refer to Section 2.10.2 for details on upgrading. Refer to Section 14.12.6 for more details and changed/new functions.

### A.27.1 Testers - Our unsung heroes

We are most indebted to the numerous members in the PostGIS community who were brave enough to test out the new features in this release. No major release can be successful without these folk.

Below are those who have been most valiant, provided very detailed and thorough bug reports, and detailed analysis.

- Andrea Peri - Lots of testing on topology, checking for correctness
- Andreas Forø Tollefsen - raster testing
- Chris English - topology stress testing loader functions
- Salvatore Larosa - topology robustness testing
- Brian Hamlin - Benchmarking (also experimental experimental branches before they are folded into core) , general testing of various
- Mike Pease - Tiger geocoder testing - very detailed reports of issues
- Tom van Tilburg - raster testing

## A.27.2 Important / Breaking Changes

**#722, #302**, Most deprecated functions removed (over 250 functions) (Regina Obe, Paul Ramsey)

Unknown SRID changed from -1 to 0. (Paul Ramsey)

-- (most deprecated in 1.2) removed non-ST variants buffer, length, intersects (and internal functions renamed) etc.

-- If you have been using deprecated functions CHANGE your apps or suffer the consequences. If you don't see a function documented -- it ain't supported or it is an internal function. Some constraints in older tables were built with deprecated functions. If you restore you may need to rebuild table constraints with `populate_geometry_columns()`. If you have applications or tools that rely on deprecated functions, please refer to [?qandaentry] for more details.

**#944** `geometry_columns` is now a view instead of a table (Paul Ramsey, Regina Obe) for tables created the old way reads (srid, type, dims) constraints for geometry columns created with type modifiers reads from column definition

**#1081, #1082, #1084, #1088** - Management functions support typmod geometry column creation functions now default to typmod creation (Regina Obe)

**#1083** `probe_geometry_columns()`, `rename_geometry_table_constraints()`, `fix_geometry_columns()`; removed - now obsolete with `geometry_column` view (Regina Obe)

**#817** Renaming old 3D functions to the convention `ST_3D` (Nicklas Avén)

**#548** (`sorta`), `ST_NumGeometries`, `ST_GeometryN` now returns 1 (or the geometry) instead of null for single geometries (Sandro Santilli, Maxime van Noppen)

## A.27.3 New Features

**KNN Gist index based centroid (<->) and box (<#>) distance operators (Paul Ramsey / funded by Vizzuality)**

Support for TIN and PolyHedralSurface and enhancement of many functions to support 3D (Olivier Courtin / Oslandia)

**Raster support integrated and documented** (Pierre Racine, Jorge Arévalo, Mateusz Loskot, Sandro Santilli, David Zwarg, Regina Obe, Bborie Park) (Company developer and funding: University Laval, Deimos Space, CadCorp, Michigan Tech Research Institute, Azavea, Paragon Corporation, UC Davis Center for Vectorborne Diseases)

Making spatial indexes 3D aware - in progress (Paul Ramsey, Mark Cave-Ayland)

Topology support improved (more functions), documented, testing (Sandro Santilli / Faunalia for RT-SIGTA), Andrea Peri, Regina Obe, Jose Carlos Martinez Llari

3D relationship and measurement support functions (Nicklas Avén)

`ST_3DDistance`, `ST_3DClosestPoint`, `ST_3DIntersects`, `ST_3DShortestLine` and more...

N-Dimensional spatial indexes (Paul Ramsey / OpenGeo)

`ST_Split` (Sandro Santilli / Faunalia for RT-SIGTA)

`ST_IsValidDetail` (Sandro Santilli / Faunalia for RT-SIGTA)

`ST_MakeValid` (Sandro Santilli / Faunalia for RT-SIGTA)

`ST_RemoveRepeatedPoints` (Sandro Santilli / Faunalia for RT-SIGTA)

`ST_GeometryN` and `ST_NumGeometries` support for non-collections (Sandro Santilli)

`ST_IsCollection` (Sandro Santilli, Maxime van Noppen)

`ST_SharedPaths` (Sandro Santilli / Faunalia for RT-SIGTA)

`ST_Snap` (Sandro Santilli)

`ST_RelateMatch` (Sandro Santilli / Faunalia for RT-SIGTA)

`ST_ConcaveHull` (Regina Obe and Leo Hsu / Paragon Corporation)

`ST_UnaryUnion` (Sandro Santilli / Faunalia for RT-SIGTA)

`ST_AsX3D` (Regina Obe / Arrival 3D funding)

`ST_OffsetCurve` (Sandro Santilli, Rafal Magda)

**`ST_GeomFromGeoJSON` (Kashif Rasul, Paul Ramsey / Vizzuality funding)**

## A.27.4 Enhancements

Made shape file loader tolerant of truncated multibyte values found in some free worldwide shapefiles (Sandro Santilli)

Lots of bug fixes and enhancements to shp2pgsql Beefing up regression tests for loaders Reproject support for both geometry and geography during import (Jeff Adams / Azavea, Mark Cave-Ayland)

pgsql2shp conversion from predefined list (Loic Dachary / Mark Cave-Ayland)

Shp-pgsql GUI loader - support loading multiple files at a time. (Mark Leslie)

Extras - upgraded tiger\_geocoder from using old TIGER format to use new TIGER shp and file structure format (Stephen Frost)

Extras - revised tiger\_geocoder to work with TIGER census 2010 data, addition of reverse geocoder function, various bug fixes, accuracy enhancements, limit max result return, speed improvements, loading routines. (Regina Obe, Leo Hsu / Paragon Corporation / funding provided by Hunter Systems Group)

Overall Documentation proofreading and corrections. (Kasif Rasul)

Cleanup PostGIS JDBC classes, revise to use Maven build. (Maria Arias de Reyna, Sandro Santilli)

## A.27.5 Bug Fixes

#1335 ST\_AddPoint returns incorrect result on Linux (Even Rouault)

## A.27.6 Release specific credits

We thank [U.S Department of State Human Information Unit \(HIU\)](#) and [Vizzuality](#) for general monetary support to get PostGIS 2.0 out the door.

## A.28 Release 1.5.4

Release date: 2012/05/07

This is a bug fix release, addressing issues that have been filed since the 1.5.3 release.

### A.28.1 Bug Fixes

#547, ST\_Contains memory problems (Sandro Santilli)

#621, Problem finding intersections with geography (Paul Ramsey)

#627, PostGIS/PostgreSQL process die on invalid geometry (Paul Ramsey)

#810, Increase accuracy of area calculation (Paul Ramsey)

#852, improve spatial predicates robustness (Sandro Santilli, Nicklas Avén)

#877, ST\_Estimated\_Extent returns NULL on empty tables (Sandro Santilli)

#1028, ST\_AsSVG kills whole postgres server when fails (Paul Ramsey)

#1056, Fix boxes of arcs and circle stroking code (Paul Ramsey)

#1121, populate\_geometry\_columns using deprecated functions (Regin Obe, Paul Ramsey)

#1135, improve testsuite predictability (Andreas 'ads' Scherbaum)

#1146, images generator crashes (bronaugh)

#1170, North Pole intersection fails (Paul Ramsey)

#1179, ST\_AsText crash with bad value (kjurka)

#1184, honour DESTDIR in documentation Makefile (Bryce L Nordgren)  
#1227, server crash on invalid GML  
#1252, SRID appearing in WKT (Paul Ramsey)  
#1264, st\_dwithin(g, g, 0) doesn't work (Paul Ramsey)  
#1344, allow exporting tables with invalid geometries (Sandro Santilli)  
#1389, wrong proj4text for SRID 31300 and 31370 (Paul Ramsey)  
#1406, shp2pgsql crashes when loading into geography (Sandro Santilli)  
#1595, fixed SRID redundancy in ST\_Line\_SubString (Sandro Santilli)  
#1596, check SRID in UpdateGeometrySRID (Mike Toews, Sandro Santilli)  
#1602, fix ST\_Polygonize to retain Z (Sandro Santilli)  
#1697, fix crash with EMPTY entries in GiST index (Paul Ramsey)  
#1772, fix ST\_Line\_Locate\_Point with collapsed input (Sandro Santilli)  
#1799, Protect ST\_Segmentize from max\_length=0 (Sandro Santilli)  
Alter parameter order in 900913 (Paul Ramsey)  
Support builds with "gmake" (Greg Troxel)

## A.29 Release 1.5.3

Release date: 2011/06/25

This is a bug fix release, addressing issues that have been filed since the 1.5.2 release. If you are running PostGIS 1.3+, a soft upgrade is sufficient otherwise a hard upgrade is recommended.

### A.29.1 Bug Fixes

#1056, produce correct bboxes for arc geometries, fixes index errors (Paul Ramsey)  
#1007, ST\_IsValid crash fix requires GEOS 3.3.0+ or 3.2.3+ (Sandro Santilli, reported by Birgit Laggner)  
#940, support for PostgreSQL 9.1 beta 1 (Regina Obe, Paul Ramsey, patch submitted by stl)  
#845, ST\_Intersects precision error (Sandro Santilli, Nicklas Avén) Reported by cdestigter  
#884, Unstable results with ST\_Within, ST\_Intersects (Chris Hodgson)  
#779, shp2pgsql -S option seems to fail on points (Jeff Adams)  
#666, ST\_DumpPoints is not null safe (Regina Obe)  
#631, Update NZ projections for grid transformation support (jpalmer)  
#630, Peculiar Null treatment in arrays in ST\_Collect (Chris Hodgson) Reported by David Bitner  
#624, Memory leak in ST\_GeogFromText (ryang, Paul Ramsey)  
#609, Bad source code in manual section 5.2 Java Clients (simoc, Regina Obe)  
#604, shp2pgsql usage touchups (Mike Toews, Paul Ramsey)  
#573 ST\_Union fails on a group of linestrings Not a PostGIS bug, fixed in GEOS 3.3.0  
#457 ST\_CollectionExtract returns non-requested type (Nicklas Avén, Paul Ramsey)  
#441 ST\_AsGeoJson Bbox on GeometryCollection error (Olivier Courtin)  
#411 Ability to backup invalid geometries (Sando Santilli) Reported by Regione Toscana  
#409 ST\_AsSVG - degraded (Olivier Courtin) Reported by Sdikiy  
#373 Documentation syntax error in hard upgrade (Paul Ramsey) Reported by psvensso

## A.30 Release 1.5.2

Release date: 2010/09/27

This is a bug fix release, addressing issues that have been filed since the 1.5.1 release. If you are running PostGIS 1.3+, a soft upgrade is sufficient otherwise a hard upgrade is recommended.

### A.30.1 Bug Fixes

Loader: fix handling of empty (0-verticed) geometries in shapefiles. (Sandro Santilli)

[#536](#), Geography ST\_Intersects, ST\_Covers, ST\_CoveredBy and Geometry ST\_Equals not using spatial index (Regina Obe, Nicklas Aven)

[#573](#), Improvement to ST\_Contains geography (Paul Ramsey)

Loader: Add support for command-q shutdown in Mac GTK build (Paul Ramsey)

[#393](#), Loader: Add temporary patch for large DBF files (Maxime Guillaud, Paul Ramsey)

[#507](#), Fix wrong OGC URN in GeoJSON and GML output (Olivier Courtin)

spatial\_ref\_sys.sql Add datum conversion for projection SRID 3021 (Paul Ramsey)

Geography - remove crash for case when all geographies are out of the estimate (Paul Ramsey)

[#469](#), Fix for array\_aggregation error (Greg Stark, Paul Ramsey)

[#532](#), Temporary geography tables showing up in other user sessions (Paul Ramsey)

[#562](#), ST\_Dwithin errors for large geographies (Paul Ramsey)

[#513](#), shape loading GUI tries to make spatial index when loading DBF only mode (Paul Ramsey)

[#527](#), shape loading GUI should always append log messages (Mark Cave-Ayland)

[#504](#), shp2pgsql should rename xmin/xmax fields (Sandro Santilli)

[#458](#), postgis\_comments being installed in contrib instead of version folder (Mark Cave-Ayland)

[#474](#), Analyzing a table with geography column crashes server (Paul Ramsey)

[#581](#), LWGEOM-expand produces inconsistent results (Mark Cave-Ayland)

[#513](#), Add dbf filter to shp2pgsql-gui and allow uploading dbf only (Paul Ramsey)

Fix further build issues against PostgreSQL 9.0 (Mark Cave-Ayland)

[#572](#), Password whitespace for Shape File (Mark Cave-Ayland)

[#603](#), shp2pgsql: "-w" produces invalid WKT for MULTI\* objects. (Mark Cave-Ayland)

## A.31 Release 1.5.1

Release date: 2010/03/11

This is a bug fix release, addressing issues that have been filed since the 1.4.1 release. If you are running PostGIS 1.3+, a soft upgrade is sufficient otherwise a hard upgrade is recommended.

---

### A.31.1 Bug Fixes

#410, update embedded bbox when applying ST\_SetPoint, ST\_AddPoint ST\_RemovePoint to a linestring (Paul Ramsey)

#411, allow dumping tables with invalid geometries (Sandro Santilli, for Regione Toscana-SIGTA)

#414, include geography\_columns view when running upgrade scripts (Paul Ramsey)

#419, allow support for multilinestring in ST\_Line\_Substring (Paul Ramsey, for Lidwala Consulting Engineers)

#421, fix computed string length in ST\_AsGML() (Olivier Courtin)

#441, fix GML generation with heterogeneous collections (Olivier Courtin)

#443, incorrect coordinate reversal in GML 3 generation (Olivier Courtin)

#450, #451, wrong area calculation for geography features that cross the date line (Paul Ramsey)

Ensure support for upcoming 9.0 PostgreSQL release (Paul Ramsey)

## A.32 Release 1.5.0

Release date: 2010/02/04

This release provides support for geographic coordinates (lat/lon) via a new GEOGRAPHY type. Also performance enhancements, new input format support (GML,KML) and general upkeep.

### A.32.1 API Stability

The public API of PostGIS will not change during minor (0.0.X) releases.

The definition of the =~ operator has changed from an exact geometric equality check to a bounding box equality check.

### A.32.2 Compatibility

GEOS, Proj4, and LibXML2 are now mandatory dependencies

The library versions below are the minimum requirements for PostGIS 1.5

PostgreSQL 8.3 and higher on all platforms

GEOS 3.1 and higher only (GEOS 3.2+ to take advantage of all features)

LibXML2 2.5+ related to new ST\_GeomFromGML/KML functionality

Proj4 4.5 and higher only

### A.32.3 New Features

Section [14.12.8](#)

Added Hausdorff distance calculations ([#209](#)) (Vincent Picavet)

Added parameters argument to ST\_Buffer operation to support one-sided buffering and other buffering styles (Sandro Santilli)

Addition of other Distance related visualization and analysis functions (Nicklas Aven)

- ST\_ClosestPoint
  - ST\_DFullyWithin
  - ST\_LongestLine
-

- ST\_MaxDistance
- ST\_ShortestLine

ST\_DumpPoints (Maxime van Noppen)

KML, GML input via ST\_GeomFromGML and ST\_GeomFromKML (Olivier Courtin)

Extract homogeneous collection with ST\_CollectionExtract (Paul Ramsey)

Add measure values to an existing linestring with ST\_AddMeasure (Paul Ramsey)

History table implementation in utils (George Silva)

Geography type and supporting functions

- Spherical algorithms (Dave Skea)
- Object/index implementation (Paul Ramsey)
- Selectivity implementation (Mark Cave-Ayland)
- Serializations to KML, GML and JSON (Olivier Courtin)
- ST\_Area, ST\_Distance, ST\_DWithin, ST\_GeogFromText, ST\_GeogFromWKB, ST\_Intersects, ST\_Covers, ST\_Buffer (Paul Ramsey)

#### A.32.4 Enhancements

Performance improvements to ST\_Distance (Nicklas Aven)

Documentation updates and improvements (Regina Obe, Kevin Neufeld)

Testing and quality control (Regina Obe)

PostGIS 1.5 support PostgreSQL 8.5 trunk (Guillaume Lelarge)

Win32 support and improvement of core shp2pgsql-gui (Mark Cave-Ayland)

In place 'make check' support (Paul Ramsey)

#### A.32.5 Bug fixes

<http://trac.osgeo.org/postgis/query?status=closed&milestone=PostGIS+1.5.0&order=priority>

### A.33 Release 1.4.0

Release date: 2009/07/24

This release provides performance enhancements, improved internal structures and testing, new features, and upgraded documentation. If you are running PostGIS 1.1+, a soft upgrade is sufficient otherwise a hard upgrade is recommended.

#### A.33.1 API Stability

As of the 1.4 release series, the public API of PostGIS will not change during minor releases.

### A.33.2 Compatibility

The versions below are the \*minimum\* requirements for PostGIS 1.4

PostgreSQL 8.2 and higher on all platforms

GEOS 3.0 and higher only

PROJ4 4.5 and higher only

### A.33.3 New Features

ST\_Union() uses high-speed cascaded union when compiled against GEOS 3.1+ (Paul Ramsey)

ST\_ContainsProperly() requires GEOS 3.1+

ST\_Intersects(), ST\_Contains(), ST\_Within() use high-speed cached prepared geometry against GEOS 3.1+ (Paul Ramsey / funded by Zonar Systems)

Vastly improved documentation and reference manual (Regina Obe & Kevin Neufeld)

Figures and diagram examples in the reference manual (Kevin Neufeld)

ST\_IsValidReason() returns readable explanations for validity failures (Paul Ramsey)

ST\_GeoHash() returns a geohash.org signature for geometries (Paul Ramsey)

GTK+ multi-platform GUI for shape file loading (Paul Ramsey)

ST\_LineCrossingDirection() returns crossing directions (Paul Ramsey)

ST\_LocateBetweenElevations() returns sub-string based on Z-ordinate. (Paul Ramsey)

Geometry parser returns explicit error message about location of syntax errors (Mark Cave-Ayland)

ST\_AsGeoJSON() return JSON formatted geometry (Olivier Courtin)

Populate\_Geometry\_Columns() -- automatically add records to geometry\_columns for TABLES and VIEWS (Kevin Neufeld)

ST\_MinimumBoundingCircle() -- returns the smallest circle polygon that can encompass a geometry (Bruce Rindahl)

### A.33.4 Enhancements

Core geometry system moved into independent library, liblwgeom. (Mark Cave-Ayland)

New build system uses PostgreSQL "pgxs" build bootstrapper. (Mark Cave-Ayland)

Debugging framework formalized and simplified. (Mark Cave-Ayland)

All build-time #defines generated at configure time and placed in headers for easier cross-platform support (Mark Cave-Ayland)

Logging framework formalized and simplified (Mark Cave-Ayland)

Expanded and more stable support for CIRCULARSTRING, COMPOUNDCURVE and CURVEPOLYGON, better parsing, wider support in functions (Mark Leslie & Mark Cave-Ayland)

Improved support for OpenSolaris builds (Paul Ramsey)

Improved support for MSVC builds (Mateusz Loskot)

Updated KML support (Olivier Courtin)

Unit testing framework for liblwgeom (Paul Ramsey)

New testing framework to comprehensively exercise every PostGIS function (Regine Obe)

Performance improvements to all geometry aggregate functions (Paul Ramsey)

Support for the upcoming PostgreSQL 8.4 (Mark Cave-Ayland, Talha Bin Rizwan)

Shp2pgsql and pgsq2shp re-worked to depend on the common parsing/unparsing code in liblwgeom (Mark Cave-Ayland)  
Use of PDF DbLatex to build PDF docs and preliminary instructions for build (Jean David Techer)  
Automated User documentation build (PDF and HTML) and Developer Doxygen Documentation (Kevin Neufeld)  
Automated build of document images using ImageMagick from WKT geometry text files (Kevin Neufeld)  
More attractive CSS for HTML documentation (Dane Springmeyer)

### A.33.5 Bug fixes

<http://trac.osgeo.org/postgis/query?status=closed&milestone=PostGIS+1.4.0&order=priority>

## A.34 Release 1.3.6

Release date: 2009/05/04

If you are running PostGIS 1.1+, a soft upgrade is sufficient otherwise a hard upgrade is recommended. This release adds support for PostgreSQL 8.4, exporting prj files from the database with shape data, some crash fixes for shp2pgsql, and several small bug fixes in the handling of "curve" types, logical error importing dbf only files, improved error handling of AddGeometryColumns.

## A.35 Release 1.3.5

Release date: 2008/12/15

If you are running PostGIS 1.1+, a soft upgrade is sufficient otherwise a hard upgrade is recommended. This release is a bug fix release to address a failure in ST\_Force\_Collection and related functions that critically affects using MapServer with LINE layers.

## A.36 Release 1.3.4

Release date: 2008/11/24

This release adds support for GeoJSON output, building with PostgreSQL 8.4, improves documentation quality and output aesthetics, adds function-level SQL documentation, and improves performance for some spatial predicates (point-in-polygon tests).

Bug fixes include removal of crashers in handling circular strings for many functions, some memory leaks removed, a linear referencing failure for measures on vertices, and more. See the NEWS file for details.

## A.37 Release 1.3.3

Release date: 2008/04/12

This release fixes bugs shp2pgsql, adds enhancements to SVG and KML support, adds a ST\_SimplifyPreserveTopology function, makes the build more sensitive to GEOS versions, and fixes a handful of severe but rare failure cases.

## A.38 Release 1.3.2

Release date: 2007/12/01

This release fixes bugs in ST\_EndPoint() and ST\_Envelope, improves support for JDBC building and OS/X, and adds better support for GML output with ST\_AsGML(), including GML3 output.

---

## A.39 Release 1.3.1

Release date: 2007/08/13

This release fixes some oversights in the previous release around version numbering, documentation, and tagging.

## A.40 Release 1.3.0

Release date: 2007/08/09

This release provides performance enhancements to the relational functions, adds new relational functions and begins the migration of our function names to the SQL-MM convention, using the spatial type (SP) prefix.

### A.40.1 Added Functionality

JDBC: Added Hibernate Dialect (thanks to Norman Barker)

Added ST\_Covers and ST\_CoveredBy relational functions. Description and justification of these functions can be found at <http://lin-ear-th-inking.blogspot.com/2007/06/subtleties-of-ogc-covers-spatial.html>

Added ST\_DWithin relational function.

### A.40.2 Performance Enhancements

Added cached and indexed point-in-polygon short-circuits for the functions ST\_Contains, ST\_Intersects, ST\_Within and ST\_Disjoint

Added inline index support for relational functions (except ST\_Disjoint)

### A.40.3 Other Changes

Extended curved geometry support into the geometry accessor and some processing functions

Began migration of functions to the SQL-MM naming convention; using a spatial type (ST) prefix.

Added initial support for PostgreSQL 8.3

## A.41 Release 1.2.1

Release date: 2007/01/11

This release provides bug fixes in PostgreSQL 8.2 support and some small performance enhancements.

### A.41.1 Changes

Fixed point-in-polygon shortcut bug in Within().

Fixed PostgreSQL 8.2 NULL handling for indexes.

Updated RPM spec files.

Added short-circuit for Transform() in no-op case.

JDBC: Fixed JTS handling for multi-dimensional geometries (thanks to Thomas Marti for hint and partial patch). Additionally, now JavaDoc is compiled and packaged. Fixed classpath problems with GCJ. Fixed pgjdbc 8.2 compatibility, losing support for jdk 1.3 and older.

---

## A.42 Release 1.2.0

Release date: 2006/12/08

This release provides type definitions along with serialization/deserialization capabilities for SQL-MM defined curved geometries, as well as performance enhancements.

### A.42.1 Changes

Added curved geometry type support for serialization/deserialization

Added point-in-polygon shortcircuit to the Contains and Within functions to improve performance for these cases.

## A.43 Release 1.1.6

Release date: 2006/11/02

This is a bugfix release, in particular fixing a critical error with GEOS interface in 64bit systems. Includes an updated of the SRS parameters and an improvement in reprojections (take Z in consideration). Upgrade is *encouraged*.

### A.43.1 Upgrading

If you are upgrading from release 1.0.3 or later follow the **soft upgrade** procedure.

If you are upgrading from a release *between 1.0.0RC6 and 1.0.2* (inclusive) and really want a live upgrade read the **upgrade section** of the 1.0.3 release notes chapter.

Upgrade from any release prior to 1.0.0RC6 requires an **hard upgrade**.

### A.43.2 Bug fixes

fixed CAPI change that broke 64-bit platforms

loader/dumper: fixed regression tests and usage output

Fixed setSRID() bug in JDBC, thanks to Thomas Marti

### A.43.3 Other changes

use Z ordinate in reprojections

spatial\_ref\_sys.sql updated to EPSG 6.11.1

Simplified Version.config infrastructure to use a single pack of version variables for everything.

Include the Version.config in loader/dumper USAGE messages

Replace hand-made, fragile JDBC version parser with Properties

## A.44 Release 1.1.5

Release date: 2006/10/13

This is an bugfix release, including a critical segfault on win32. Upgrade is *encouraged*.

---

### A.44.1 Upgrading

If you are upgrading from release 1.0.3 or later follow the [soft upgrade](#) procedure.

If you are upgrading from a release *between 1.0.0RC6 and 1.0.2* (inclusive) and really want a live upgrade read the [upgrade section](#) of the 1.0.3 release notes chapter.

Upgrade from any release prior to 1.0.0RC6 requires an [hard upgrade](#).

### A.44.2 Bug fixes

Fixed MingW link error that was causing pgsq2shp to segfault on Win32 when compiled for PostgreSQL 8.2

fixed nullpointer Exception in Geometry.equals() method in Java

Added EJB3Spatial.odt to fulfill the GPL requirement of distributing the "preferred form of modification"

Removed obsolete synchronization from JDBC Jts code.

Updated heavily outdated README files for shp2pgsql/pgsq2shp by merging them with the manpages.

Fixed version tag in jdbc code that still said "1.1.3" in the "1.1.4" release.

### A.44.3 New Features

Added -S option for non-multi geometries to shp2pgsql

## A.45 Release 1.1.4

Release date: 2006/09/27

This is an bugfix release including some improvements in the Java interface. Upgrade is *encouraged*.

### A.45.1 Upgrading

If you are upgrading from release 1.0.3 or later follow the [soft upgrade](#) procedure.

If you are upgrading from a release *between 1.0.0RC6 and 1.0.2* (inclusive) and really want a live upgrade read the [upgrade section](#) of the 1.0.3 release notes chapter.

Upgrade from any release prior to 1.0.0RC6 requires an [hard upgrade](#).

### A.45.2 Bug fixes

Fixed support for PostgreSQL 8.2

Fixed bug in collect() function discarding SRID of input

Added SRID match check in MakeBox2d and MakeBox3d

Fixed regress tests to pass with GEOS-3.0.0

Improved pgsq2shp run concurrency.

### A.45.3 Java changes

reworked JTS support to reflect new upstream JTS developers' attitude to SRID handling. Simplifies code and drops build depend on GNU trove.

Added EJB2 support generously donated by the "Geodetix s.r.l. Company"

Added EJB3 tutorial / examples donated by Norman Barker <nbarker@ittvis.com>

Reorganized java directory layout a little.

---

## A.46 Release 1.1.3

Release date: 2006/06/30

This is an bugfix release including also some new functionalities (most notably long transaction support) and portability enhancements. Upgrade is *encouraged*.

### A.46.1 Upgrading

If you are upgrading from release 1.0.3 or later follow the **soft upgrade** procedure.

If you are upgrading from a release *between 1.0.0RC6 and 1.0.2* (inclusive) and really want a live upgrade read the **upgrade section** of the 1.0.3 release notes chapter.

Upgrade from any release prior to 1.0.0RC6 requires an **hard upgrade**.

### A.46.2 Bug fixes / correctness

BUGFIX in distance(poly,poly) giving wrong results.

BUGFIX in pgsq2shp successful return code.

BUGFIX in shp2pgsql handling of MultiLine WKT.

BUGFIX in affine() failing to update bounding box.

WKT parser: forbidden construction of multigeometries with EMPTY elements (still supported for GEOMETRYCOLLECTION).

### A.46.3 New functionalities

NEW Long Transactions support.

NEW DumpRings() function.

NEW AsHEXEWKB(geom, XDRINDR) function.

### A.46.4 JDBC changes

Improved regression tests: MultiPoint and scientific ordinates

Fixed some minor bugs in jdbc code

Added proper accessor functions for all fields in preparation of making those fields private later

### A.46.5 Other changes

NEW regress test support for loader/dumper.

Added --with-proj-libdir and --with-geos-libdir configure switches.

Support for build Tru64 build.

Use Jade for generating documentation.

Don't link pgsq2shp to more libs then required.

Initial support for PostgreSQL 8.2.

---

## A.47 Release 1.1.2

Release date: 2006/03/30

This is an bugfix release including some new functions and portability enhancements. Upgrade is *encouraged*.

### A.47.1 Upgrading

If you are upgrading from release 1.0.3 or later follow the **soft upgrade** procedure.

If you are upgrading from a release *between 1.0.0RC6 and 1.0.2* (inclusive) and really want a live upgrade read the **upgrade section** of the 1.0.3 release notes chapter.

Upgrade from any release prior to 1.0.0RC6 requires an **hard upgrade**.

### A.47.2 Bug fixes

BUGFIX in SnapToGrid() computation of output bounding box

BUGFIX in EnforceRHR()

jdbc2 SRID handling fixes in JTS code

Fixed support for 64bit archs

### A.47.3 New functionalities

Regress tests can now be run *\*before\** postgis installation

New affine() matrix transformation functions

New rotate{,X,Y,Z}() function

Old translating and scaling functions now use affine() internally

Embedded access control in estimated\_extent() for builds against postgresql >= 8.0.0

### A.47.4 Other changes

More portable ./configure script

Changed ./run\_test script to have more sane default behaviour

## A.48 Release 1.1.1

Release date: 2006/01/23

This is an important Bugfix release, upgrade is *highly recommended*. Previous version contained a bug in postgis\_restore.pl preventing **hard upgrade** procedure to complete and a bug in GEOS-2.2+ connector preventing GeometryCollection objects to be used in topological operations.

### A.48.1 Upgrading

If you are upgrading from release 1.0.3 or later follow the **soft upgrade** procedure.

If you are upgrading from a release *between 1.0.0RC6 and 1.0.2* (inclusive) and really want a live upgrade read the **upgrade section** of the 1.0.3 release notes chapter.

Upgrade from any release prior to 1.0.0RC6 requires an **hard upgrade**.

---

## A.48.2 Bug fixes

Fixed a premature exit in `postgis_restore.pl`

BUGFIX in geometrycollection handling of GEOS-C-API connector

Solaris 2.7 and MingW support improvements

BUGFIX in `line_locate_point()`

Fixed handling of postgresql paths

BUGFIX in `line_substring()`

Added support for localized cluster in regress tester

## A.48.3 New functionalities

New Z and M interpolation in `line_substring()`

New Z and M interpolation in `line_interpolate_point()`

added `NumInteriorRing()` alias due to OpenGIS ambiguity

## A.49 Release 1.1.0

Release date: 2005/12/21

This is a Minor release, containing many improvements and new things. Most notably: build procedure greatly simplified; `transform()` performance drastically improved; more stable GEOS connectivity (CAPI support); lots of new functions; draft topology support.

It is *highly recommended* that you upgrade to GEOS-2.2.x before installing PostGIS, this will ensure future GEOS upgrades won't require a rebuild of the PostGIS library.

### A.49.1 Credits

This release includes code from Mark Cave Ayland for caching of proj4 objects. Markus Schaber added many improvements in his JDBC2 code. Alex Bodnaru helped with PostgreSQL source dependency relief and provided Debian specfiles. Michael Fuhr tested new things on Solaris arch. David Techer and Gerald Fenoy helped testing GEOS C-API connector. Hartmut Tschauner provided code for the `azimuth()` function. Devrim GUNDUZ provided RPM specfiles. Carl Anderson helped with the new area building functions. See the [credits](#) section for more names.

### A.49.2 Upgrading

If you are upgrading from release 1.0.3 or later you *DO NOT* need a dump/reload. Simply sourcing the new `lwpostgis_upgrade.sql` script in all your existing databases will work. See the [soft upgrade](#) chapter for more information.

If you are upgrading from a release *between 1.0.0RC6 and 1.0.2* (inclusive) and really want a live upgrade read the [upgrade section](#) of the 1.0.3 release notes chapter.

Upgrade from any release prior to 1.0.0RC6 requires an [hard upgrade](#).

### A.49.3 New functions

scale() and transscale() companion methods to translate()

line\_substring()

line\_locate\_point()

M(point)

LineMerge(geometry)

shift\_longitude(geometry)

azimuth(geometry)

locate\_along\_measure(geometry, float8)

locate\_between\_measures(geometry, float8, float8)

SnapToGrid by point offset (up to 4d support)

BuildArea(any\_geometry)

OGC BdPolyFromText(linestring\_wkt, srid)

OGC BdMPolyFromText(linestring\_wkt, srid)

RemovePoint(linestring, offset)

ReplacePoint(linestring, offset, point)

### A.49.4 Bug fixes

Fixed memory leak in polygonize()

Fixed bug in lwgeom\_as\_anytype cast functions

Fixed USE\_GEOS, USE\_PROJ and USE\_STATS elements of postgis\_version() output to always reflect library state.

### A.49.5 Function semantic changes

SnapToGrid doesn't discard higher dimensions

Changed Z() function to return NULL if requested dimension is not available

### A.49.6 Performance improvements

Much faster transform() function, caching proj4 objects

Removed automatic call to fix\_geometry\_columns() in AddGeometryColumns() and update\_geometry\_stats()

### A.49.7 JDBC2 works

Makefile improvements

JTS support improvements

Improved regression test system

Basic consistency check method for geometry collections

Support for (Hex)(E)wkb

Autoprobing DriverWrapper for HexWKB / EWKT switching

fix compile problems in ValueSetter for ancient jdk releases.

fix EWKT constructors to accept SRID=4711; representation

added preliminary read-only support for java2d geometries

---

### A.49.8 Other new things

Full autoconf-based configuration, with PostgreSQL source dependency relief

GEOS C-API support (2.2.0 and higher)

Initial support for topology modelling

Debian and RPM specfiles

New lwpostgis\_upgrade.sql script

### A.49.9 Other changes

JTS support improvements

Stricter mapping between DBF and SQL integer and string attributes

Wider and cleaner regression test suite

old jdbc code removed from release

obsoleted direct use of postgis\_proc\_upgrade.pl

scripts version unified with release version

## A.50 Release 1.0.6

Release date: 2005/12/06

Contains a few bug fixes and improvements.

### A.50.1 Upgrading

If you are upgrading from release 1.0.3 or later you *DO NOT* need a dump/reload.

If you are upgrading from a release *between 1.0.0RC6 and 1.0.2* (inclusive) and really want a live upgrade read the [upgrade section](#) of the 1.0.3 release notes chapter.

Upgrade from any release prior to 1.0.0RC6 requires an [hard upgrade](#).

### A.50.2 Bug fixes

Fixed palloc(0) call in collection deserializer (only gives problem with --enable-cassert)

Fixed bbox cache handling bugs

Fixed geom\_accum(NULL, NULL) segfault

Fixed segfault in addPoint()

Fixed short-allocation in lwcollection\_clone()

Fixed bug in segmentize()

Fixed bbox computation of SnapToGrid output

### A.50.3 Improvements

Initial support for postgresql 8.2

Added missing SRID mismatch checks in GEOS ops

---

## A.51 Release 1.0.5

Release date: 2005/11/25

Contains memory-alignment fixes in the library, a segfault fix in loader's handling of UTF8 attributes and a few improvements and cleanups.

### Note

Return code of shp2pgsql changed from previous releases to conform to unix standards (return 0 on success).

---

### A.51.1 Upgrading

If you are upgrading from release 1.0.3 or later you *DO NOT* need a dump/reload.

If you are upgrading from a release *between 1.0.0RC6 and 1.0.2* (inclusive) and really want a live upgrade read the [upgrade section](#) of the 1.0.3 release notes chapter.

Upgrade from any release prior to 1.0.0RC6 requires an [hard upgrade](#).

### A.51.2 Library changes

Fixed memory alignment problems

Fixed computation of null values fraction in analyzer

Fixed a small bug in the getPoint4d\_p() low-level function

Speedup of serializer functions

Fixed a bug in force\_3dm(), force\_3dz() and force\_4d()

### A.51.3 Loader changes

Fixed return code of shp2pgsql

Fixed back-compatibility issue in loader (load of null shapefiles)

Fixed handling of trailing dots in dbf numerical attributes

Segfault fix in shp2pgsql (utf8 encoding)

### A.51.4 Other changes

Schema aware postgis\_proc\_upgrade.pl, support for postgres 7.2+

New "Reporting Bugs" chapter in manual

## A.52 Release 1.0.4

Release date: 2005/09/09

Contains important bug fixes and a few improvements. In particular, it fixes a memory leak preventing successful build of GiST indexes for large spatial tables.

---

### A.52.1 Upgrading

If you are upgrading from release 1.0.3 you *DO NOT* need a dump/reload.

If you are upgrading from a release *between 1.0.0RC6 and 1.0.2* (inclusive) and really want a live upgrade read the [upgrade section](#) of the 1.0.3 release notes chapter.

Upgrade from any release prior to 1.0.0RC6 requires an [hard upgrade](#).

### A.52.2 Bug fixes

Memory leak plugged in GiST indexing

Segfault fix in transform() handling of proj4 errors

Fixed some proj4 texts in spatial\_ref\_sys (missing +proj)

Loader: fixed string functions usage, reworked NULL objects check, fixed segfault on MULTILINESTRING input.

Fixed bug in MakeLine dimension handling

Fixed bug in translate() corrupting output bounding box

### A.52.3 Improvements

Documentation improvements

More robust selectivity estimator

Minor speedup in distance()

Minor cleanups

GiST indexing cleanup

Looser syntax acceptance in box3d parser

## A.53 Release 1.0.3

Release date: 2005/08/08

Contains some bug fixes - *including a severe one affecting correctness of stored geometries* - and a few improvements.

### A.53.1 Upgrading

Due to a bug in a bounding box computation routine, the upgrade procedure requires special attention, as bounding boxes cached in the database could be incorrect.

An [hard upgrade](#) procedure (dump/reload) will force recomputation of all bounding boxes (not included in dumps). This is *required* if upgrading from releases prior to 1.0.0RC6.

If you are upgrading from versions 1.0.0RC6 or up, this release includes a perl script (utils/rebuild\_bbox\_caches.pl) to force recomputation of geometries' bounding boxes and invoke all operations required to propagate eventual changes in them (geometry statistics update, reindexing). Invoke the script after a make install (run with no args for syntax help). Optionally run utils/postgis\_proc\_upgrade.pl to refresh postgis procedures and functions signatures (see [Soft upgrade](#)).

### A.53.2 Bug fixes

Severe bugfix in lwgeom's 2d bounding box computation

Bugfix in WKT (-w) POINT handling in loader

Bugfix in dumper on 64bit machines

Bugfix in dumper handling of user-defined queries

Bugfix in create\_undef.pl script

### A.53.3 Improvements

Small performance improvement in canonical input function

Minor cleanups in loader

Support for multibyte field names in loader

Improvement in the postgis\_restore.pl script

New rebuild\_bbox\_caches.pl util script

## A.54 Release 1.0.2

Release date: 2005/07/04

Contains a few bug fixes and improvements.

### A.54.1 Upgrading

If you are upgrading from release 1.0.0RC6 or up you *DO NOT* need a dump/reload.

Upgrading from older releases requires a dump/reload. See the [upgrading](#) chapter for more informations.

### A.54.2 Bug fixes

Fault tolerant btree ops

Memory leak plugged in pg\_error

Rtree index fix

Cleaner build scripts (avoided mix of CFLAGS and CXXFLAGS)

### A.54.3 Improvements

New index creation capabilities in loader (-I switch)

Initial support for postgresql 8.1dev

## A.55 Release 1.0.1

Release date: 2005/05/24

Contains a few bug fixes and some improvements.

---

### A.55.1 Upgrading

If you are upgrading from release 1.0.0RC6 or up you *DO NOT* need a dump/reload.

Upgrading from older releases requires a dump/reload. See the [upgrading](#) chapter for more informations.

### A.55.2 Library changes

BUGFIX in 3d computation of length\_spheroid()

BUGFIX in join selectivity estimator

### A.55.3 Other changes/additions

BUGFIX in shp2pgsql escape functions

better support for concurrent postgis in multiple schemas

documentation fixes

jdbc2: compile with "-target 1.2 -source 1.2" by default

NEW -k switch for pgsq2shp

NEW support for custom createdb options in postgis\_restore.pl

BUGFIX in pgsq2shp attribute names unicity enforcement

BUGFIX in Paris projections definitions

postgis\_restore.pl cleanups

## A.56 Release 1.0.0

Release date: 2005/04/19

Final 1.0.0 release. Contains a few bug fixes, some improvements in the loader (most notably support for older postgis versions), and more docs.

### A.56.1 Upgrading

If you are upgrading from release 1.0.0RC6 you *DO NOT* need a dump/reload.

Upgrading from any other precedent release requires a dump/reload. See the [upgrading](#) chapter for more informations.

### A.56.2 Library changes

BUGFIX in transform() releasing random memory address

BUGFIX in force\_3dm() allocating less memory then required

BUGFIX in join selectivity estimator (defaults, leaks, tuplecount, sd)

### A.56.3 Other changes/additions

BUGFIX in shp2pgsql escape of values starting with tab or single-quote

NEW manual pages for loader/dumper

NEW shp2pgsql support for old (HWGEOM) postgis versions

NEW -p (prepare) flag for shp2pgsql

NEW manual chapter about OGC compliancy enforcement

NEW autoconf support for JTS lib

BUGFIX in estimator testers (support for LWGEOM and schema parsing)

## A.57 Release 1.0.0RC6

Release date: 2005/03/30

Sixth release candidate for 1.0.0. Contains a few bug fixes and cleanups.

### A.57.1 Upgrading

You need a dump/reload to upgrade from precedent releases. See the [upgrading](#) chapter for more informations.

### A.57.2 Library changes

BUGFIX in multi()

early return [when noop] from multi()

### A.57.3 Scripts changes

dropped {x,y}{min,max}(box2d) functions

### A.57.4 Other changes

BUGFIX in postgis\_restore.pl scrip

BUGFIX in dumper's 64bit support

## A.58 Release 1.0.0RC5

Release date: 2005/03/25

Fifth release candidate for 1.0.0. Contains a few bug fixes and a improvements.

### A.58.1 Upgrading

If you are upgrading from release 1.0.0RC4 you *DO NOT* need a dump/reload.

Upgrading from any other precedent release requires a dump/reload. See the [upgrading](#) chapter for more informations.

---

### A.58.2 Library changes

BUGFIX (segfaulting) in box3d computation (yes, another!).

BUGFIX (segfaulting) in estimated\_extent().

### A.58.3 Other changes

Small build scripts and utilities refinements.

Additional performance tips documented.

## A.59 Release 1.0.0RC4

Release date: 2005/03/18

Fourth release candidate for 1.0.0. Contains bug fixes and a few improvements.

### A.59.1 Upgrading

You need a dump/reload to upgrade from precedent releases. See the [upgrading](#) chapter for more informations.

### A.59.2 Library changes

BUGFIX (segfaulting) in geom\_accum().

BUGFIX in 64bit architectures support.

BUGFIX in box3d computation function with collections.

NEW subselects support in selectivity estimator.

Early return from force\_collection.

Consistency check fix in SnapToGrid().

Box2d output changed back to 15 significant digits.

### A.59.3 Scripts changes

NEW distance\_sphere() function.

Changed get\_proj4\_from\_srid implementation to use PL/PGSQL instead of SQL.

### A.59.4 Other changes

BUGFIX in loader and dumper handling of MultiLine shapes

BUGFIX in loader, skipping all but first hole of polygons.

jdbc2: code cleanups, Makefile improvements

FLEX and YACC variables set `*after*` pgsq Makefile.global is included and only if the pgsq `*stripped*` version evaluates to the empty string

Added already generated parser in release

Build scripts refinements

improved version handling, central Version.config

improvements in postgis\_restore.pl

---

## A.60 Release 1.0.0RC3

Release date: 2005/02/24

Third release candidate for 1.0.0. Contains many bug fixes and improvements.

### A.60.1 Upgrading

You need a dump/reload to upgrade from precedent releases. See the [upgrading](#) chapter for more informations.

### A.60.2 Library changes

BUGFIX in transform(): missing SRID, better error handling.

BUGFIX in memory alignment handling

BUGFIX in force\_collection() causing mapserver connector failures on simple (single) geometry types.

BUGFIX in GeometryFromText() missing to add a bbox cache.

reduced precision of box2d output.

prefixed DEBUG macros with PGIS\_ to avoid clash with pgsq1 one

plugged a leak in GEOS2POSTGIS converter

Reduced memory usage by early releasing query-context pallocated one.

### A.60.3 Scripts changes

BUGFIX in 72 index bindings.

BUGFIX in probe\_geometry\_columns() to work with PG72 and support multiple geometry columns in a single table

NEW bool::text cast

Some functions made IMMUTABLE from STABLE, for performance improvement.

### A.60.4 JDBC changes

jdbc2: small patches, box2d/3d tests, revised docs and license.

jdbc2: bug fix and testcase in for pgjdbc 8.0 type autoregistration

jdbc2: Removed use of jdk1.4 only features to enable build with older jdk releases.

jdbc2: Added support for building against pg72jdbc2.jar

jdbc2: updated and cleaned makefile

jdbc2: added BETA support for jts geometry classes

jdbc2: Skip known-to-fail tests against older PostGIS servers.

jdbc2: Fixed handling of measured geometries in EWKT.

### A.60.5 Other changes

new performance tips chapter in manual

documentation updates: pgsq172 requirement, lwpostgis.sql

few changes in autoconf

BUILDDATE extraction made more portable

fixed spatial\_ref\_sys.sql to avoid vacuuming the whole database.

spatial\_ref\_sys: changed Paris entries to match the ones distributed with 0.x.

## A.61 Release 1.0.0RC2

Release date: 2005/01/26

Second release candidate for 1.0.0 containing bug fixes and a few improvements.

### A.61.1 Upgrading

You need a dump/reload to upgrade from precedent releases. See the [upgrading](#) chapter for more informations.

### A.61.2 Library changes

BUGFIX in pointarray box3d computation

BUGFIX in distance\_spheroid definition

BUGFIX in transform() missing to update bbox cache

NEW jdbc driver (jdbc2)

GEOMETRYCOLLECTION(EMPTY) syntax support for backward compatibility

Faster binary outputs

Stricter OGC WKB/WKT constructors

### A.61.3 Scripts changes

More correct STABLE, IMMUTABLE, STRICT uses in lwpostgis.sql

stricter OGC WKB/WKT constructors

### A.61.4 Other changes

Faster and more robust loader (both i18n and not)

Initial autoconf script

## A.62 Release 1.0.0RC1

Release date: 2005/01/13

This is the first candidate of a major postgis release, with internal storage of postgis types redesigned to be smaller and faster on indexed queries.

### A.62.1 Upgrading

You need a dump/reload to upgrade from precedent releases. See the [upgrading](#) chapter for more informations.

---

## A.62.2 Changes

Faster canonical input parsing.

Lossless canonical output.

EWKB Canonical binary IO with PG>73.

Support for up to 4d coordinates, providing lossless shapefile->postgis->shapefile conversion.

New function: UpdateGeometrySRID(), AsGML(), SnapToGrid(), ForceRHR(), estimated\_extent(), accum().

Vertical positioning indexed operators.

JOIN selectivity function.

More geometry constructors / editors.

PostGIS extension API.

UTF8 support in loader.
